

Status codes

HTTP status codes indicate the result of a request. They provide information about whether the request was successful, encountered an error, or needs further action.

Errors.- Consumer passes invalid data to the API, and the API correctly rejects this. Errors are commonly related with level 400 status codes and do not contribute to API availability.

Faults.- API fails to return a response to a valid request. Are commonly related with level 500 status codes and do not contribute to API availability.

Status codes that contribute to API availability are those that indicate a successful response or a temporary redirection. These status codes indicate that the API is operational and can handle incoming requests.

HTTP Method Overview by Use case

<p>Creating resources (server)</p> <p>POST api/authors – {author}</p> <p>201 [author], 404</p> <p>POST api/authors/{authorId} can never be successful (404 or 409)</p> <p>Create a new resource for adding a collection in one go</p> <p>POST api/authorcollections – {authorCollection}</p>	<p>Creating resources (consumer)</p> <p>PUT api/authors/{authorId} – {author}</p> <p>201 [author]</p> <p>PATCH api/authors/{authorId} – {JsonPatchDocument on author}</p> <p>201 [author]</p>
<p>Reading resources</p> <p>GET api/authors</p> <p>200 [{author}], 404</p> <p>GET api/authors/{authorId}</p> <p>200 [author], 404</p>	<p>Deleting resources</p> <p>DELETE api/authors/{authorId}</p> <p>204, 404</p> <p>DELETE api/authors</p> <p>204, 404</p> <p><i>Rarely implemented</i></p>
<p>Updating resources (full)</p> <p>PUT api/authors/{authorId} – {author}</p> <p>200 [author], 204, 404</p> <p>PUT api/authors – [{author}, {author}]</p> <p>200 [{author}, {author}], 204, 404</p> <p><i>Rarely implemented</i></p>	<p>Updating resources (partial)</p> <p>PATCH api/authors/{authorId} – {JsonPatchDocument on author}</p> <p>200 [author], 204, 404</p> <p>PATCH api/authors – {JsonPatchDocument on authors}</p> <p>200 [{author}, {author}], 204, 404</p> <p><i>Rarely implemented</i></p>

Web APIs Models

API Models must be : Well-Named, Well-Factored, Well-Sized and Stable

Resource Names that clients understand, that don't reveal internal architecture, reveal intention.

Don't combine multiple concepts into a single model

Large models with many sub-records are resource intensive for both client and server, provide tools like paging and filtering.

Your most used-resources and models need to be the most stable, make changes in an additive fashion

Designing the Outer Facing Contract

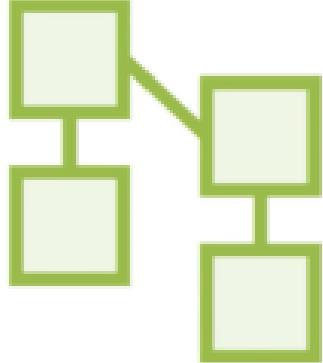

Resource identifier
<http://host/api/authors>

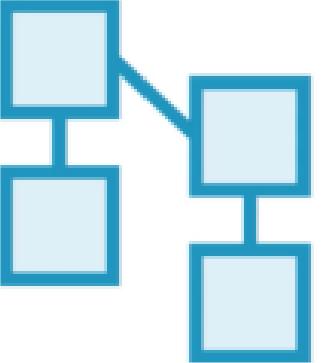

HTTP method
<https://datatracker.ietf.org/doc/html/rfc9110>

Payload (representation: media types)

Outer Facing Model vs. Entity Model

The entity model represents database rows as objects

The outer facing model represents what's sent over the wire

Outer facing model (AuthorDto)

Guid Id
string Name
int Age

Entity model (Author)

Guid Id
string FirstName
string LastName
DateTimeOffset DateOfBirth

Example

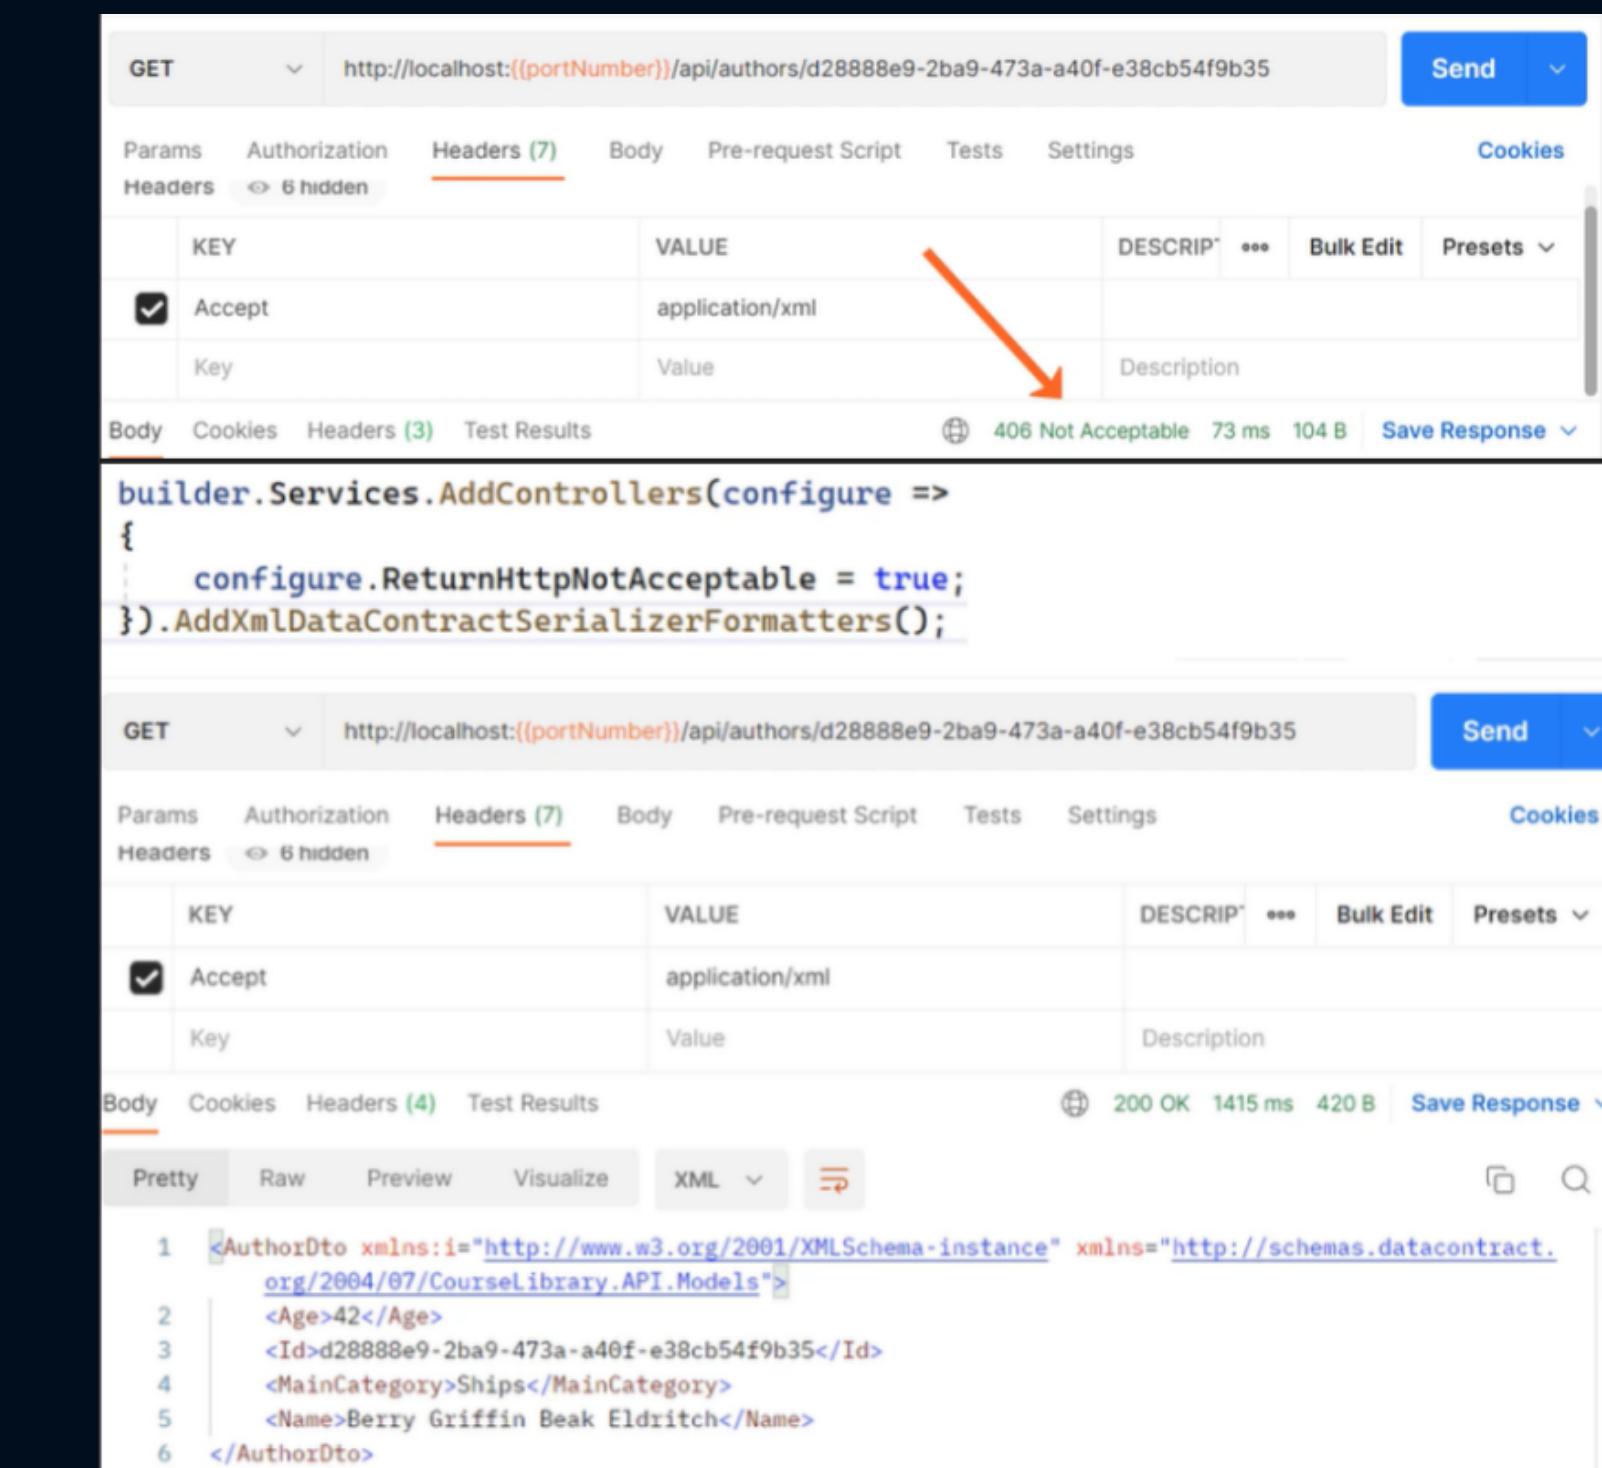

Content negotiation and formatters

Content Negotiation in ASP.NET Core is the process of selecting the appropriate response format (media type) based on the client's preferences and the available formats supported by the server. It enables the server to return responses in various data formats, such as JSON, XML, or custom formats, based on the client's requested format.

```
builder.Services.AddControllers(configure =>
{
    configure.ReturnHttpNotAcceptable = true;
})
    .AddNewtonsoftJson(setupAction =>
{
    setupAction.SerializerSettings.ContractResolver =
        new CamelCasePropertyNamesContractResolver();
})
    .AddXmlDataContractSerializerFormatters();

builder.Services.AddControllers(configure =>
{
    configure.ReturnHttpNotAcceptable = true;
})
    .AddXmlDataContractSerializerFormatters()
    .AddJsonOptions(options =>
{
    options.JsonSerializerOptions.PropertyNamingPolicy =
        JsonNamingPolicy.CamelCase;
});
```

Add content negotiation and formatters

The screenshot shows two requests in the Postman interface. The top request is a GET to `http://localhost:(portNumber)/api/authors/d28888e9-2ba9-473a-a40f-e38cb54f9b35`. The Headers tab shows an `Accept` header set to `application/xml`. The response status is 406 Not Acceptable, and the response body is empty. The bottom request is also a GET to the same URL. The Headers tab shows an `Accept` header set to `application/json`. The response status is 200 OK, and the response body is a JSON object representing an AuthorDto:

```
1 <AuthorDto xmlns:i="http://www.w3.org/2001/XMLSchema-instance" xmlns="http://schemas.datacontract.org/2004/07/CourseLibrary.API.Models">
2 <Age>42</Age>
3 <Id>d28888e9-2ba9-473a-a40f-e38cb54f9b35</Id>
4 <MainCategory>Ships</MainCategory>
5 <Name>Berry Griffin Beak Eldritch</Name>
6 </AuthorDto>
```

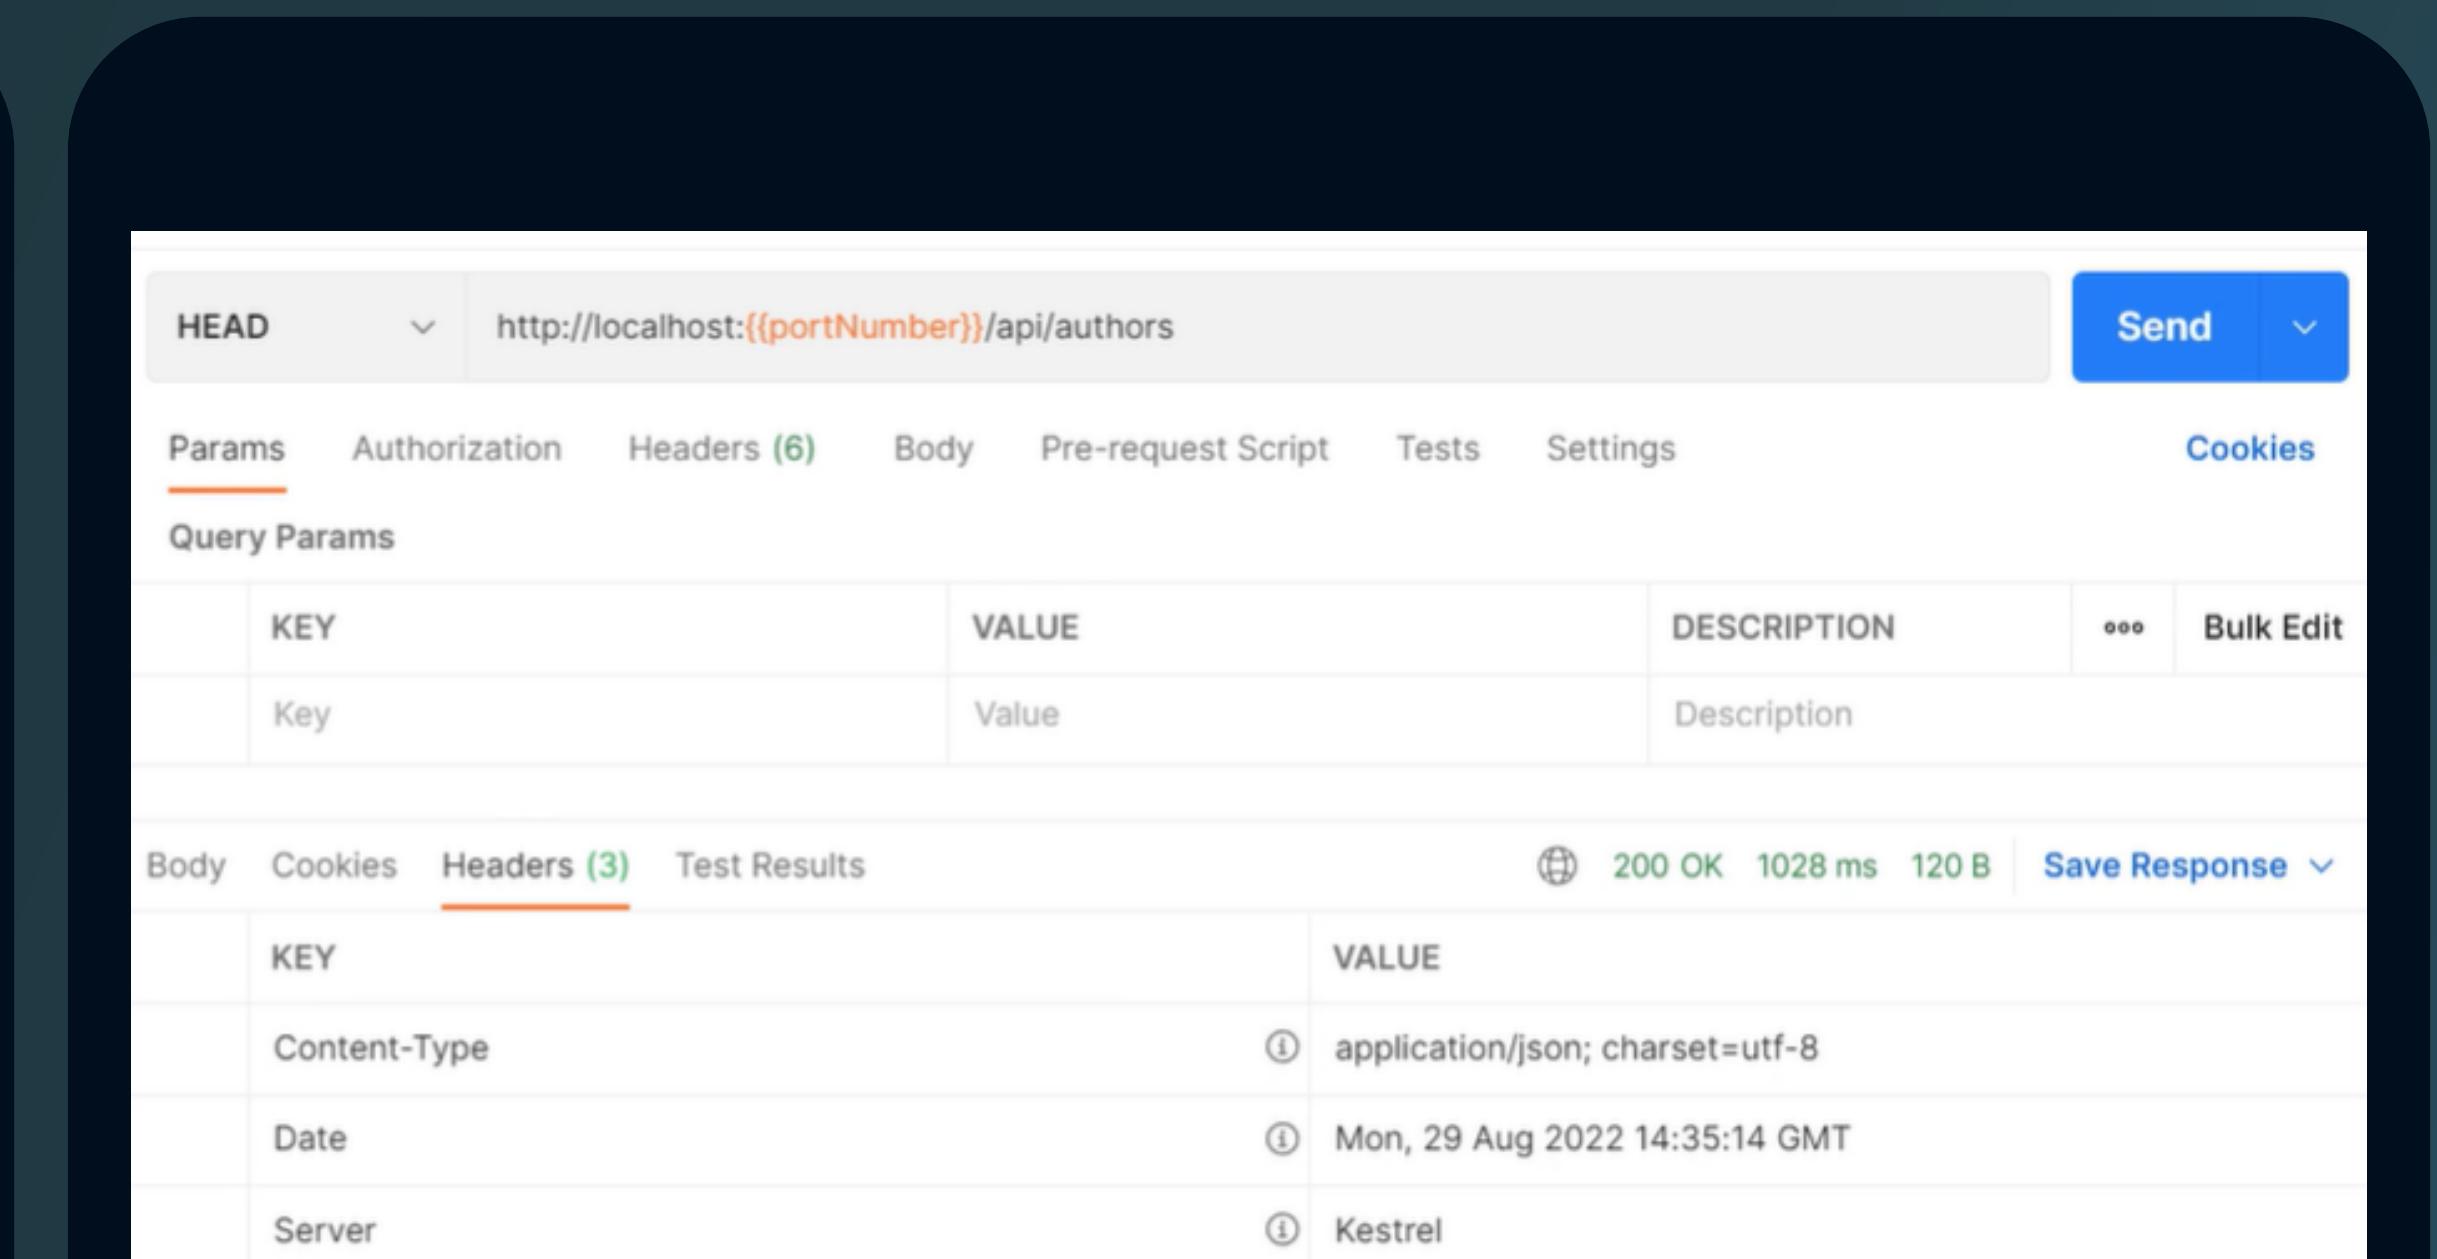

Content negotiation and formatters example

Add support for Head

The HEAD request method is similar to the GET request but only requests the response headers and not the actual content. It is useful when you want to retrieve metadata or check the existence of a resource without downloading the entire payload. The server responds with the same headers that would be returned for a corresponding GET request, but the response body is empty.

```
[HttpGet]  
[HttpHead]  
0 references  
public async Task<ActionResult<IEnumerable<AuthorDto>>> GetAuthors()  
{  
    // throw new Exception("Test exception");  
  
    // get authors from repo  
    var authorsFromRepo = await _courseLibraryRepository  
        .GetAuthorsAsync();  
  
    // return them  
    return Ok(_mapper.Map<IEnumerable<AuthorDto>>(authorsFromRepo));  
}
```

Head operation

HEAD http://localhost:(portNumber)/api/authors

Params Authorization Headers (6) Body Pre-request Script Tests Settings Cookies

Server	Kestrel

Head request example

CORS implementation

CORS is an essential security feature that helps protect web applications from unauthorized access while still allowing legitimate cross-origin requests when required.

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddMvc();

    services.AddCors(options =>
    {
        options.AddPolicy("MySingleOriginCorsPolicy", builder =>
            builder.WithOrigins("http://localhost:5001"));
    });

    services.AddCors(options =>
    {
        options.AddPolicy("MySingleOriginCorsPolicy", builder =>
            builder.WithOrigins("http://localhost:5001")
                .WithMethods("GET"));
    });
}
```

Configure Cors

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    loggerFactory.AddConsole();

    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }

    app.UseCors("MySingleOriginCorsPolicy");

    //app.UseCors(builder =>
    //{
    //    builder.WithOrigins("http://localhost:5001");
    //});
}
```

Use Cors

```
[Route("api/data")]
[EnableCors("MySingleOriginCorsPolicy")]
public class DataController : Controller
{
    [HttpGet]
    [EnableCors("MySingleOriginCorsPolicy")]
    public string GetSomeData()
    {
        return "some data here...";
    }
}

[Route("api/data")]
[EnableCors("MySingleOriginCorsPolicy")]
public class DataController : Controller
{
    [HttpGet]
    [DisableCors]
    public string GetSomeData()
    {
        return "some data here...";
    }
}
```

Explicit CORS use

Add support for Options

Is used to retrieve the communication options available for a given resource or server. It allows the client to determine which HTTP methods and headers are allowed on a specific endpoint. The server responds with an "Allow" header, which lists the HTTP methods that the server supports for the requested resource. It is often used as part of the Cross-Origin Resource Sharing (CORS) mechanism, allowing browsers to check if a particular cross-origin request is allowed before actually making it.

```
public void ConfigureServices(IServiceCollection services)
{
    // Other configurations ...
    services.AddCors(options =>
    {
        options.AddPolicy("AllowSpecificOrigins", builder =>
        {
            builder.WithOrigins("https://example.com",
                "https://api.example.com") // Specify allowed origins
                .WithMethods("GET", "POST", "PUT", "DELETE") // Specify allowed HTTP methods
                .WithHeaders("Content-Type", "Authorization");
        });
    });
    // Other configurations ...
}

public void Configure(IApplicationBuilder app, IWebHostEnvironment env)
{
    // Other configurations ...
    app.UseCors("AllowSpecificOrigins");
    // Other configurations ...
}
```

Options implementation with CORS

```
[HttpOptions()]
0 references
public IActionResult GetAuthorsOptions()
{
    Response.Headers.Add("Allow", "GET, HEAD, POST, OPTIONS");
    return Ok();
}
```

Options endpoint manual implementation

Healthcheck

Health checks play a crucial role in ensuring the availability and reliability of APIs. Health checks are a mechanism that allows applications to periodically check the status and health of their components, including API endpoints, databases, services, and other dependencies. By regularly monitoring the health of these components, you can proactively detect and respond to issues, improving overall API availability.

```
- □ ×  
public void ConfigureServices(IServiceCollection services)  
{  
    ... // Other configurations ...  
    services.AddHealthChecks();  
    ... // Other configurations ...  
}  
  
public void Configure(IApplicationBuilder app, IWebHostEnvironment env)  
{  
    ... // Other configurations ...  
    app.UseRouting();  
    app.UseEndpoints(endpoints =>  
    {  
        endpoints.MapControllers();  
        endpoints.MapHealthChecks("/health"); // Endpoint for  
        health checks  
    });  
    ... // Other configurations ...  
}
```

Add Healthcheck

HATEOAS

stands for "Hypermedia as the Engine of Application State," is a principle of RESTful API design that emphasizes the use of hypermedia links in API responses to enable clients to navigate and interact with the API dynamically. The idea behind HATEOAS is to make the API self-descriptive, allowing clients to discover available actions and resources without prior knowledge of the API's URL structure.

```
{ ...  
  "links": [ ...,  
    {  
      "href": "http://host/api/authors?pageNumber=1&pageSize=10",  
      "rel": "previous-page",  
      "method": "GET"  
    },  
    {  
      "href": "http://host/api/authors?pageNumber=3&pageSize=10",  
      "rel": "next-page",  
      "method": "GET"  
    }]  
}  
  
{ ...  
  "links": [ ...,  
    {  
      "href": "http://host/api/authors/{authorId}/courses/{courseId}",  
      "rel": "update-course-partial",  
      "method": "PATCH"  
    },  
    {  
      "href": "http://host/api/authors/{authorId}/courses/{courseId}",  
      "rel": "delete-course",  
      "method": "DELETE"  
    },  
    {  
      "href": "http://host/api/coursereservations",  
      "rel": "reserve-course",  
      "method": "POST"  
  ]}  
}
```

Example

```
{ "id": "5b1c2b4d-48c7-402a-80c3-cc796ad49c6b",  
  "title": "Commandeering a ship without getting caught",  
  "description": "Commandeering a ship in rough waters ...",  
  "authorId": "d28888e9-2ba9-473a-a40f-e38cb54f9b35",  
  "numberOfAvailablePlaces": 10,  
  "content": "mature" }
```

Issues Without HATEOAS

Intrinsic knowledge of the API contract is required
An additional rule, or a change of a rule, breaks consumers of the API
The API cannot evolve separately of consuming applications

Richardson Maturity model

The Richardson Maturity Model is a model introduced by Leonard Richardson to assess the level of maturity and adherence to RESTful principles in Web API design.

POST (info on data)
<http://host/myapi>

POST (author to create)
<http://host/myapi>

Level 0 (The Swamp of POX)

HTTP protocol is used for remote interaction
... the rest of the protocol isn't used as it should be

RPC-style implementations (SOAP, often seen when using WCF)

POST
<http://host/api/authors>

POST
<http://host/api/authors/{id}>

Level 1 (Resources)

Each resource is mapped to a URI
HTTP methods aren't used as they should be

GET
<http://host/api/authors>
200 Ok (authors)

POST (author representation)
<http://host/api/authors>
201 Created (author)

Level 2 (Verbs)

Correct HTTP verbs are used
Correct status codes are used

GET
<http://host/api/authors>
200 Ok (authors + links that
drive application state)

Level 3 (Hypermedia)

The API supports Hypermedia as the Engine of Application State (HATEOAS)

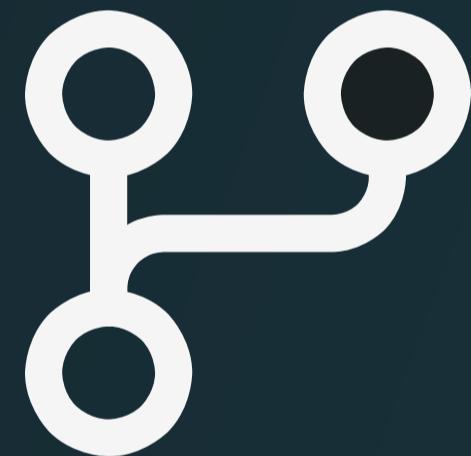

Introduces discoverability

Demo

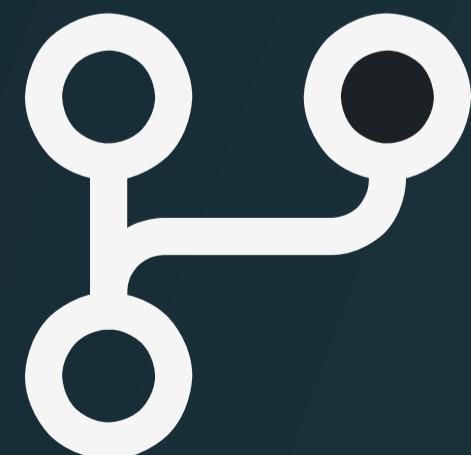

We will check the following:

What status code are handle it
How to configure Swagger to show different status codes
Head, options and Healthcheck

You can check the following Repository(ies) for some examples:
[DocumentingASPNetCore6API](#)

You can check the following Repository for some examples:
[C# fundamentals](#)

Task

Exercise/ Homework

This is a continuation of the previous exercise. Add validations for the controllers implemented:

- Add support for Healthcheck
- Add support for CORS
- Handle correctly your response codes
