

# Common Type System

The Common Type System (CTS) is a set of rules and definitions that describe the data types that can be used in C#. The CTS defines primitive data types, structures, classes, enumerations, reference types, and value types.

# Boxing and unboxing

Boxing is the process of converting a primitive type into an object type.

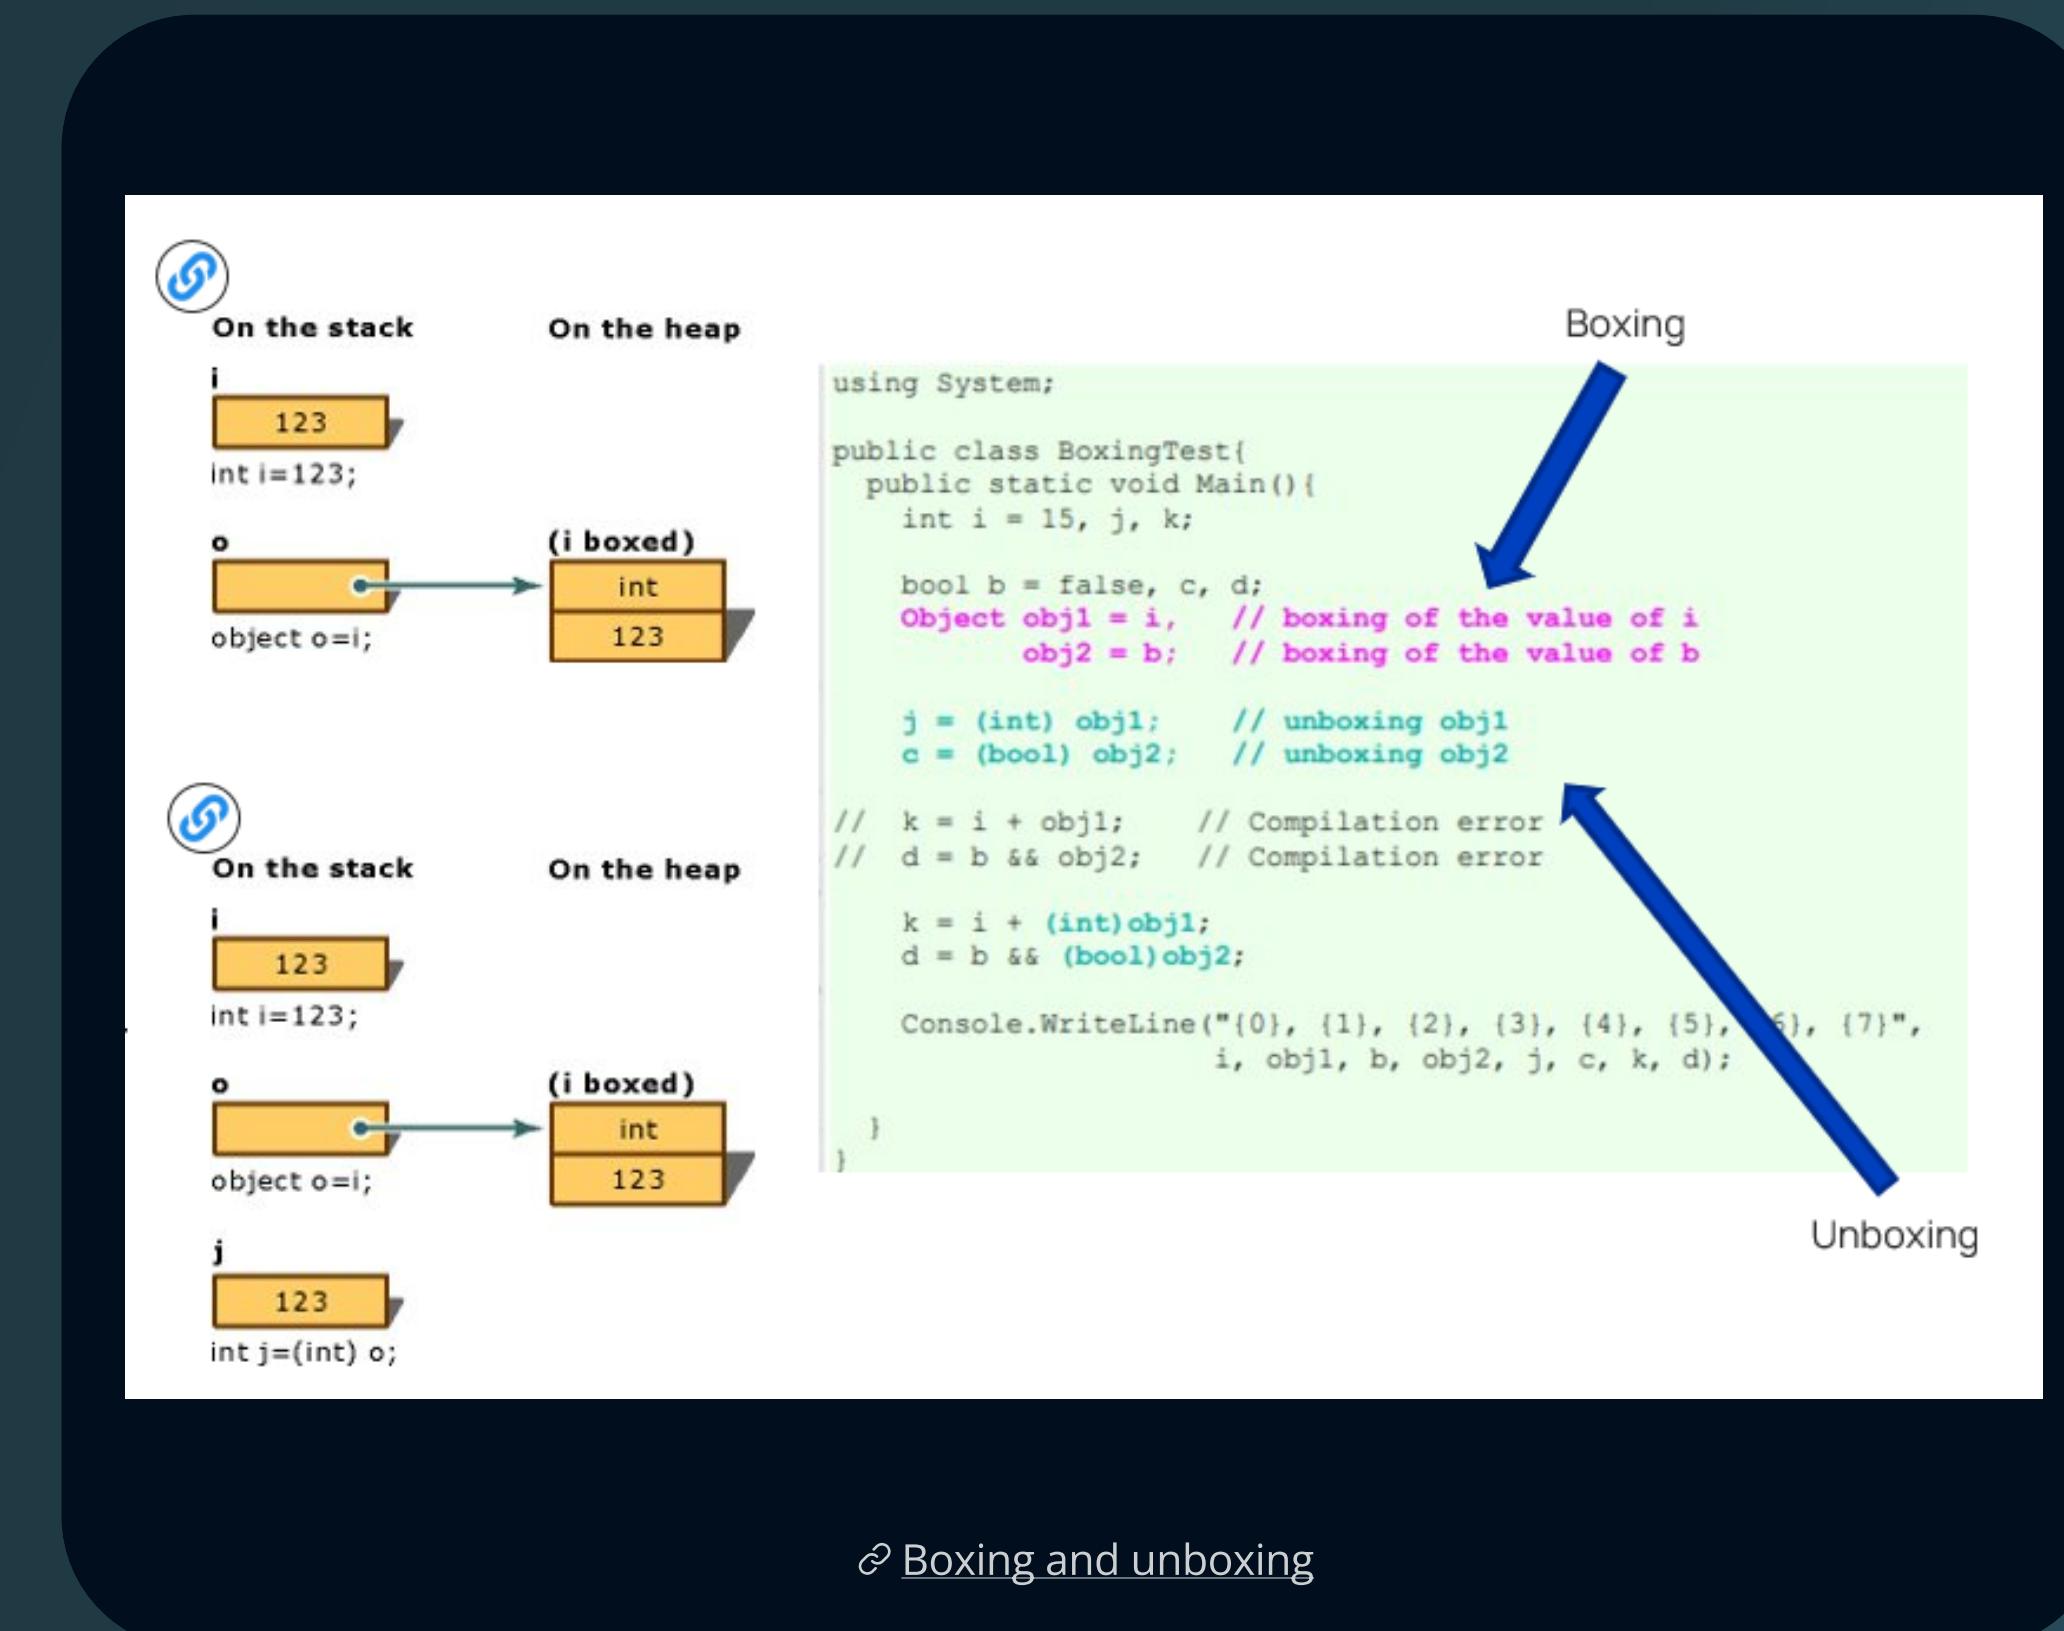

Unboxing, is the process of converting an object type into a primitive type.

This is one of the building blocks of the unification of the Type System, which was implemented for the C# programming language. It allows different types of data to be used interchangeably by conversion.

What happens when boxing : An example of this would be an int being converted to an System.Int32 object by the compiler. It will be stored on the heap rather than on the stack with the other primitive types

What happens when you unbox a variable: you are performing an explicit conversion from an object type to a primitive type.

For more information here is some [documentation](#)

# Conversions

There are two main types of programming languages. The first one is statically typed, the second one is dynamically typed, statically typed languages are usually faster than dynamically typed ones.

More information in this [documentation](#)

```
-- □ X  
// Implicit conversion  
int age = 12;  
double era = age;
```

## Implicit conversion

This is the safest type of casting. No data is lost. E.g converting a smaller to larger integral types

```
-- □ X  
// Explicit conversion  
double pi = 3.14;  
int roundedPi = (int)pi;
```

## **Explicit conversion**

Involves the cast operator. It is associated with information loss. E.g Convert from larger precision datatype to lower precision

## **User defined conversion**

They can be introduced by declaring conversion operators in class and struct types. These user-defined conversions convert a value from its type, called source type, to another type which is called target type.

## **Conversion with helper classes**

Similar to the previous conversion type

# Conversion examples

## Implicit conversion

```
int a = 10;
double b = a; // an int can be safely cast into a
               double
WriteLine(b); // Result is 10
```

## Explicit conversion

```
double c = 9.8;
int d = c; // compiler gives an error for this line Compilation error
WriteLine(d);
```

```
int d = (int)c;
WriteLine(d); // d is 9 losing the .8 part
```

```
using static System.Console; ← Importing
namespace
```

## Using System.Convert

```
using static System.Convert;
double g = 9.8;
int h =ToInt32(g); // a method of System.Convert
WriteLine($"g is {g} and h is {h}");
```

Result  
g is 9.8 and h is 10 ←

Using cast operator  
Result is 9

# is, as and typeof

Alongside the [cast operators](#), these operators and expressions perform type checking or type conversion. More information in the [documentation](#)

## is operator

Checks if the run-time type of an expression result is compatible with a given type. The is operator also tests an expression result against a pattern.

The is operator doesn't consider user-defined conversions.

## as operator

Explicitly converts the result of an expression to a given reference or nullable value type.

If the conversion isn't possible, the as operator returns null. Unlike a [cast expression](#), the as operator never throws an exception.  
Considers only reference, nullable, boxing, and unboxing conversions.

## typeof operator

Obtains the [System.Type](#) instance for a type.

The argument to the typeof operator must be the name of a type or a type parameter.

The argument mustn't be a type that requires metadata annotations (dynamic, string?)

# Value and reference types

Data types can be classified into two large groups : Value types and reference types

Fixed size, allocated by compiler on stack

Value is copied to this memory location

Independent instances/copies

Value change does not affect other copies

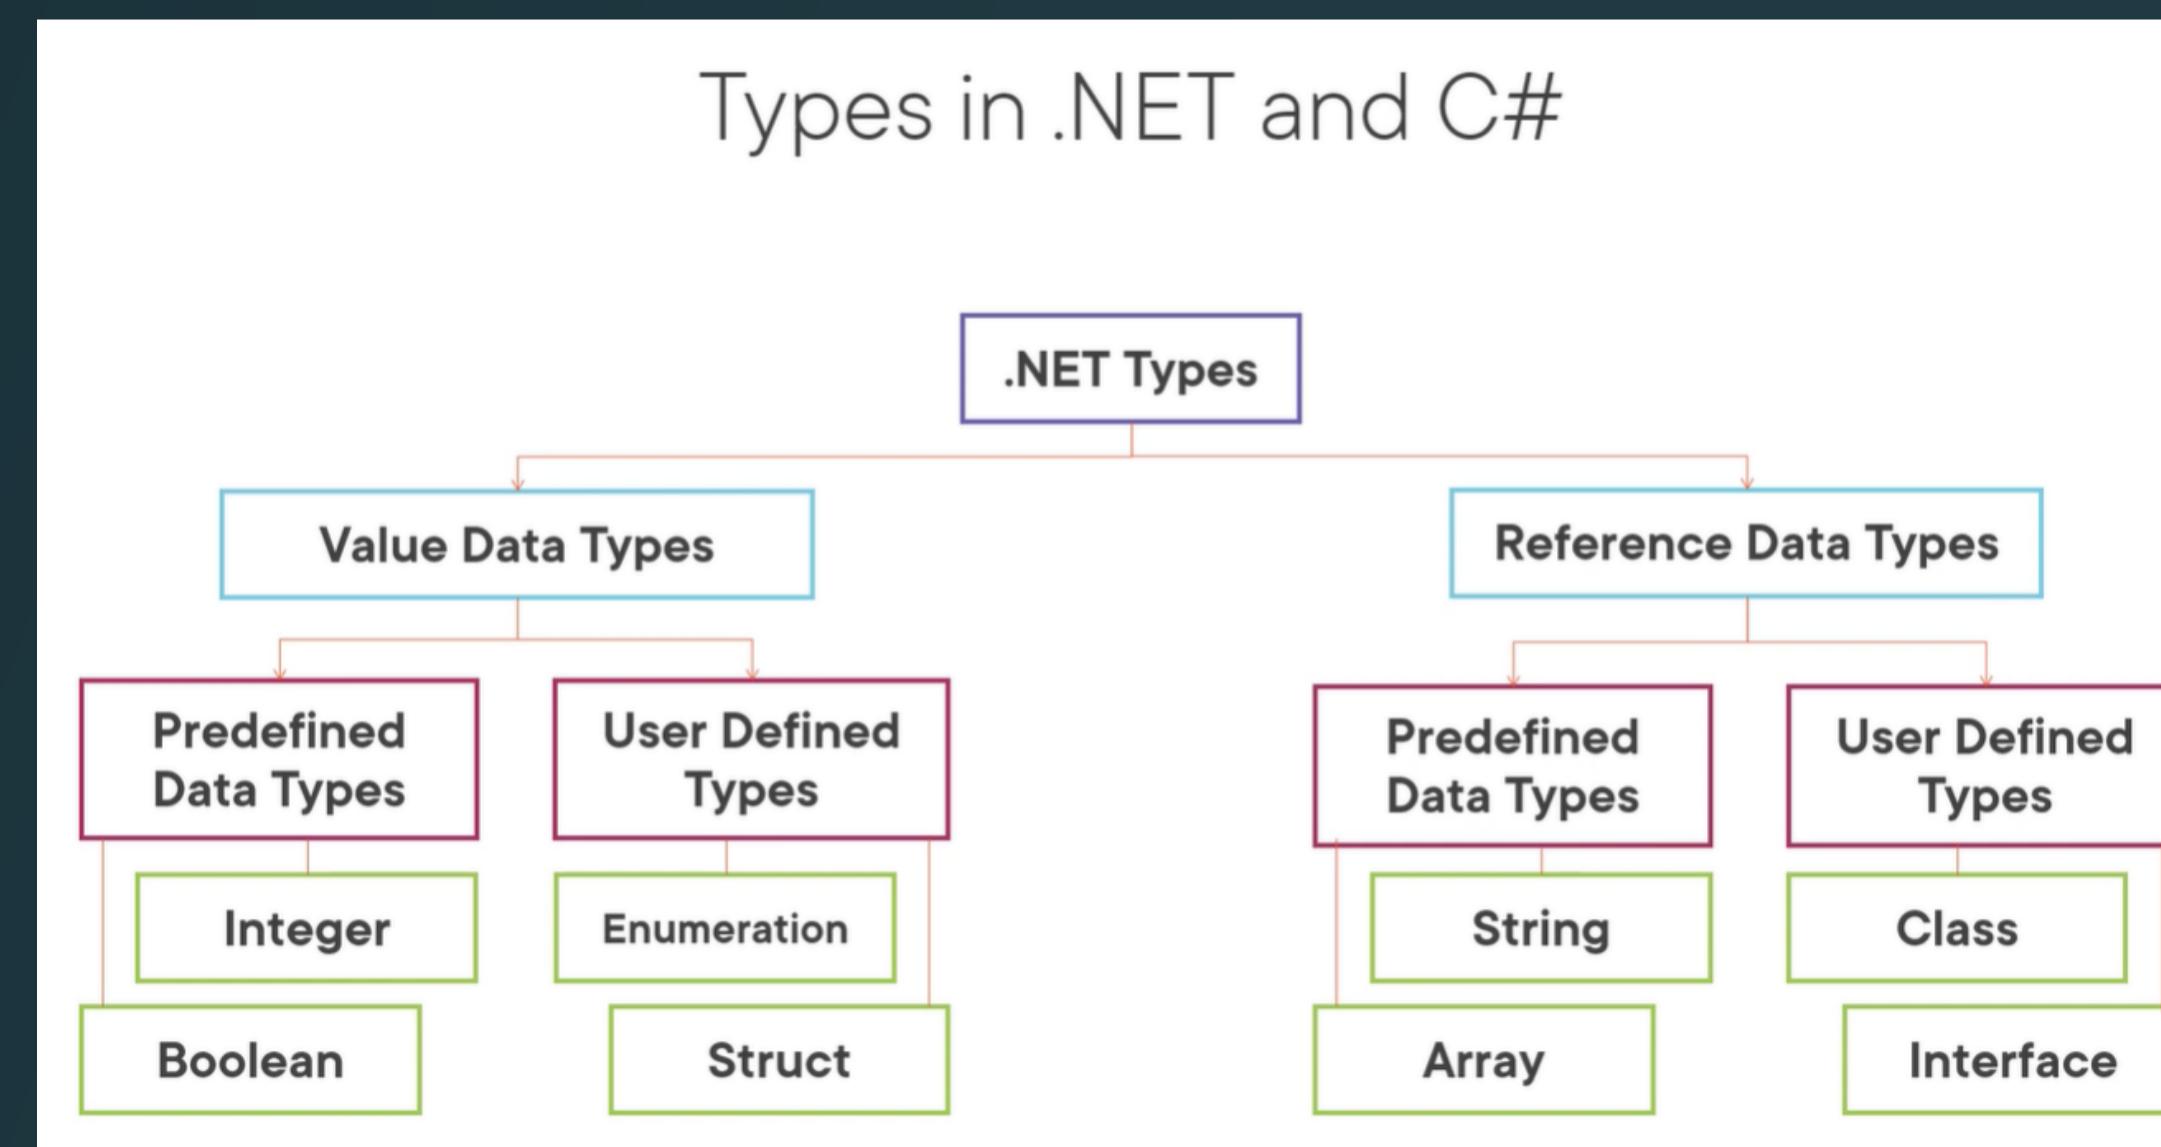

Stack contains just a pointer to the memory address

Classes and collections are reference types

Single shared instance

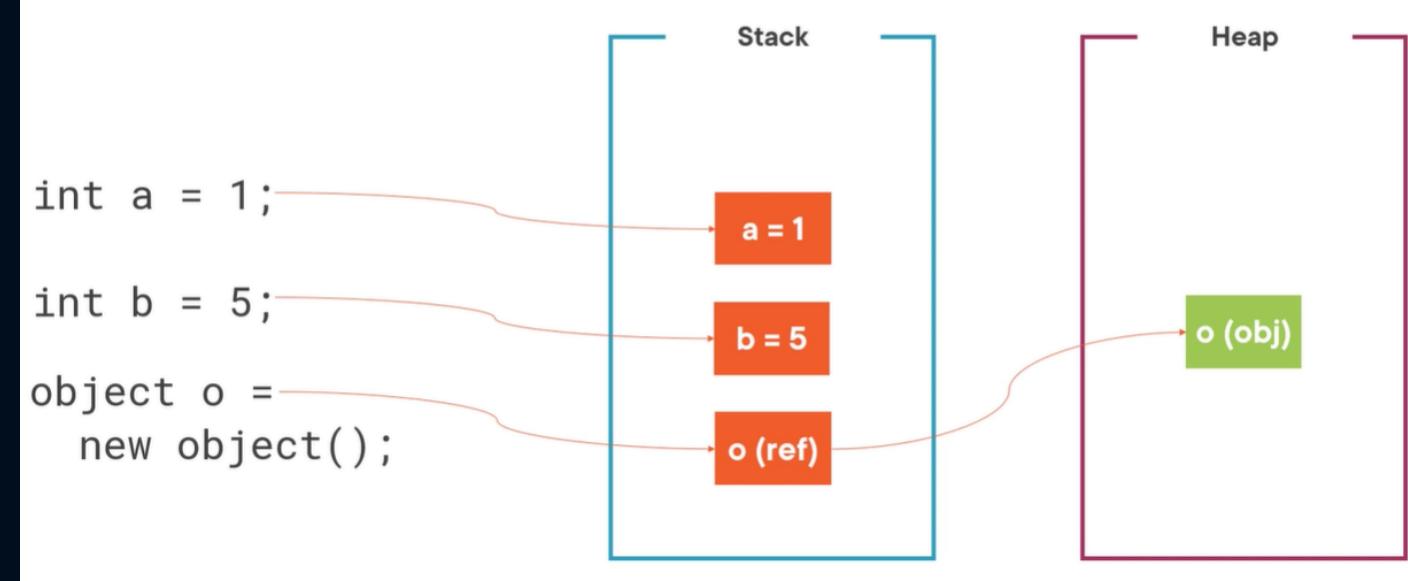

Reference may point to nothing (null)

Null checking code may be required

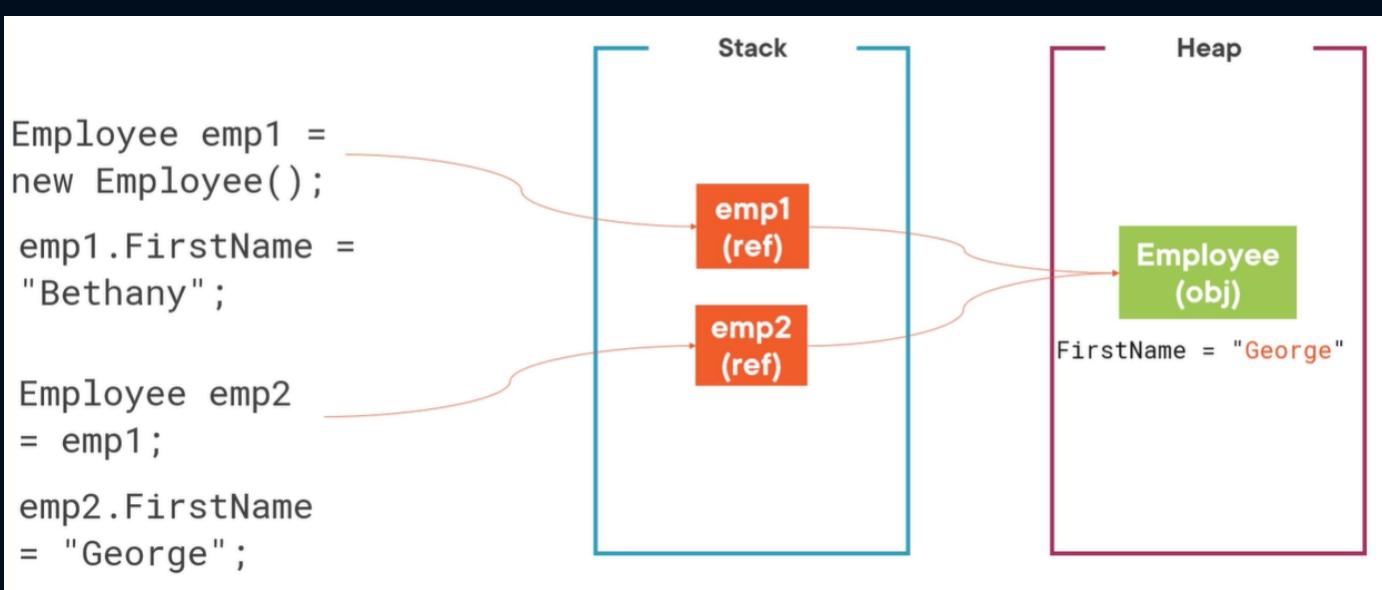

# Value and reference types when creating copies

## Working with Reference Types

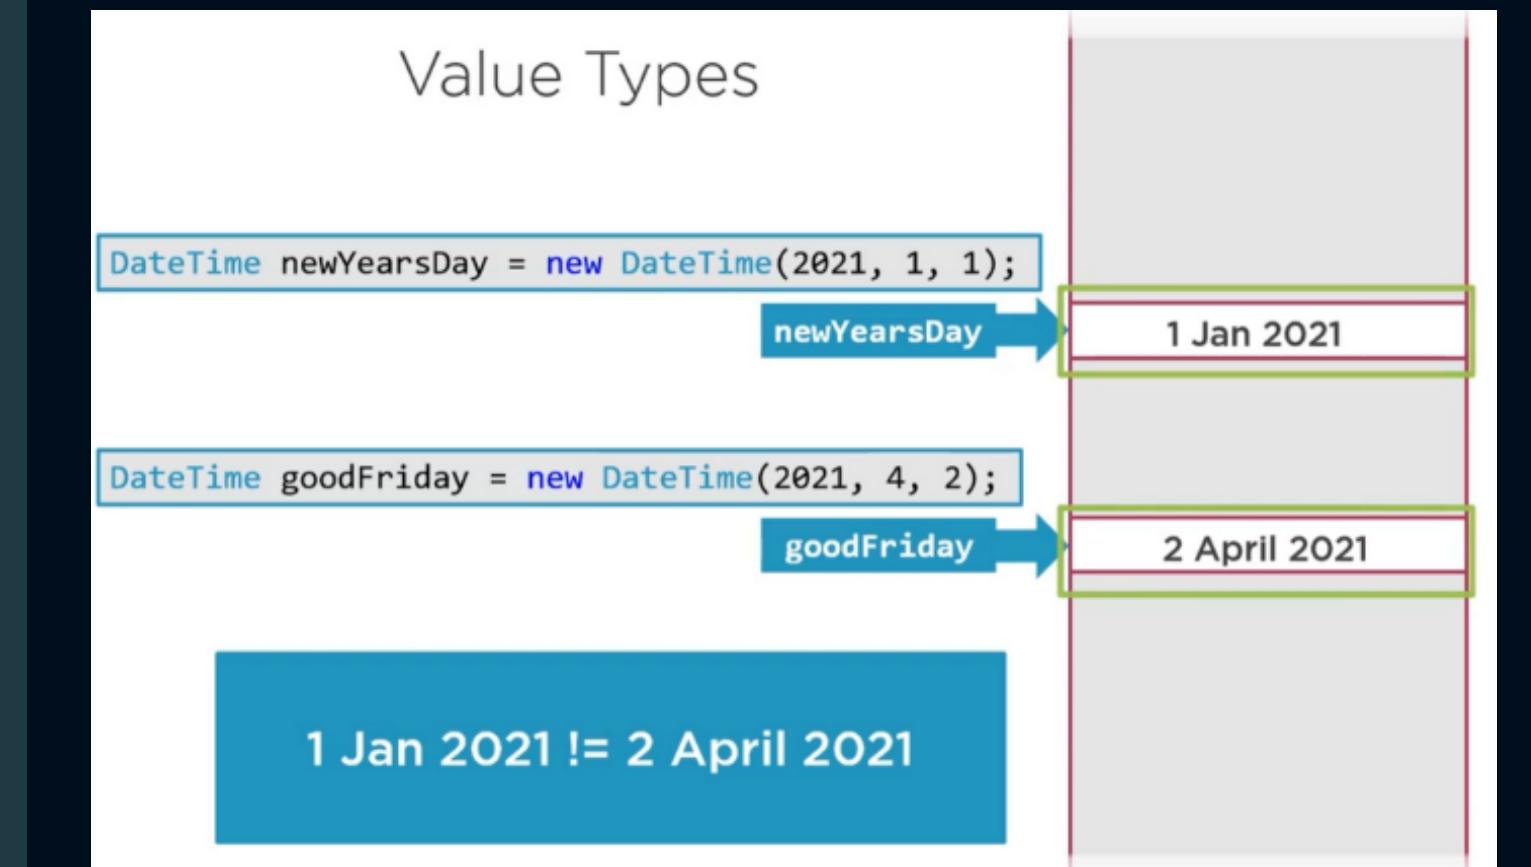

Reference types and value types  
assignment

Copying using a reference type

## Value Types

Using a value type

# Visual studio commands

## Some useful command to use in Visual Studio

**Ctrl + TAB**

Shows active files in editor

**Alt + F7**

Shows active tools

**Ctrl + G**

Specify a line number in the active editor

**Ctrl + ,**

Navigate to any file in the solution

**Ctrl + I + T**

Search for types in the current editor

**Ctrl + T**

Search anything in the solution

**Ctrl + -**

Go to the previous position (similar to Undo but for navigation)

**Ctrl + Shift + -**

Go back to the position (Re do but for navigation)

**F12**

When selecting a type, to see the definition

**Alt+F12**

When selecting a type, to peek definition

**Ctrl + G**

Use the Visual studio general search

**Ctrl + .**

Show refactoring actions

**Ctrl + F**

Search in file

**Ctrl + H**

Find and replace

**Ctrl + M + O**

Expand file to show details

**Ctrl + K + E**

Run cleanup configuration

**Ctrl + R + R**

Rename selected value

**Ctrl + R + G**

Clean usings and reorder

# Some keyboard shortcuts

Some benefits of debugging: clearly understand flow and conditions in code. Help me code easier to read / maintain / understand. Improve reliability of code or application

## Keyboard Shortcuts - Debugging

**F5** -> Start (Debugging)

**Ctrl-F5** -> Start without Debugging

**F10** -> Step Over

**F11** -> Step Into

**F5** -> Continue

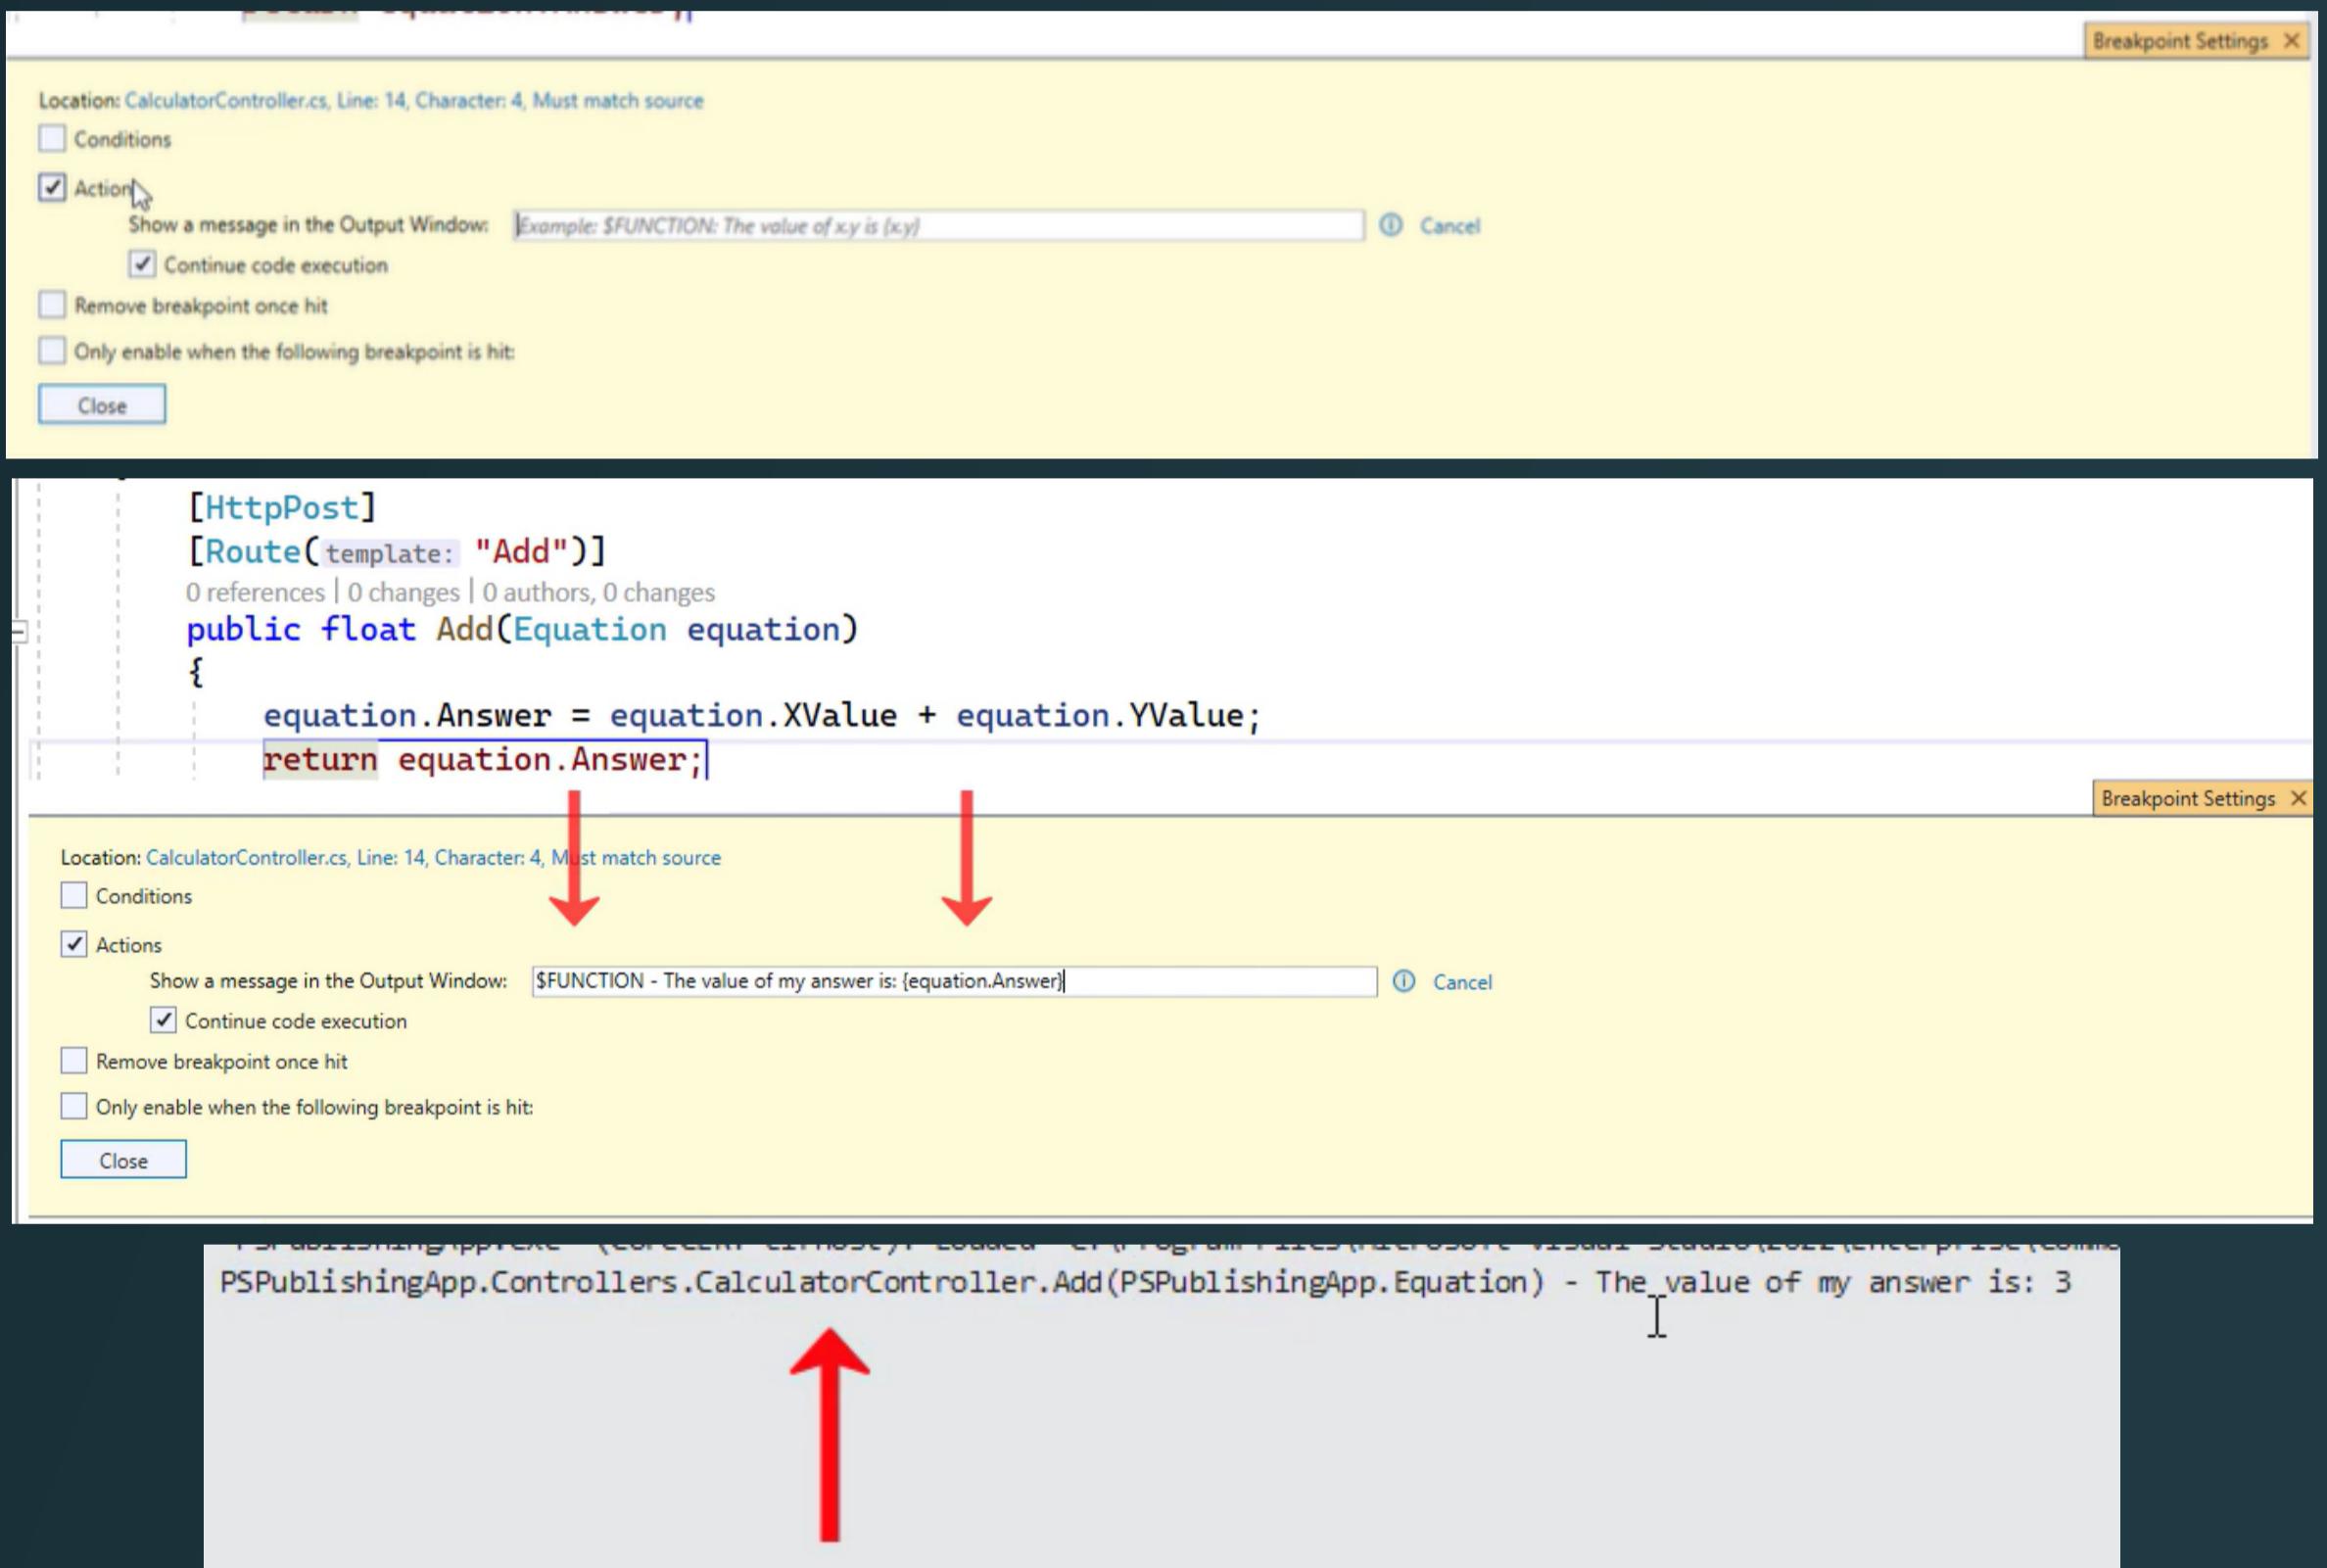

**Shift-F9** -> Quick Watch

**F9** -> Toggle Breakpoint

**Alt-F10** -> Hot Reload

# Tracepoints

Breakpoints in Visual Studio IDE are essential debugging tools that allow developers to pause the execution of their code at specific points to inspect variables, step through the code, and troubleshoot issues.

Using action inside breakpoints

Using Function metadata when breakpoint hit

Result

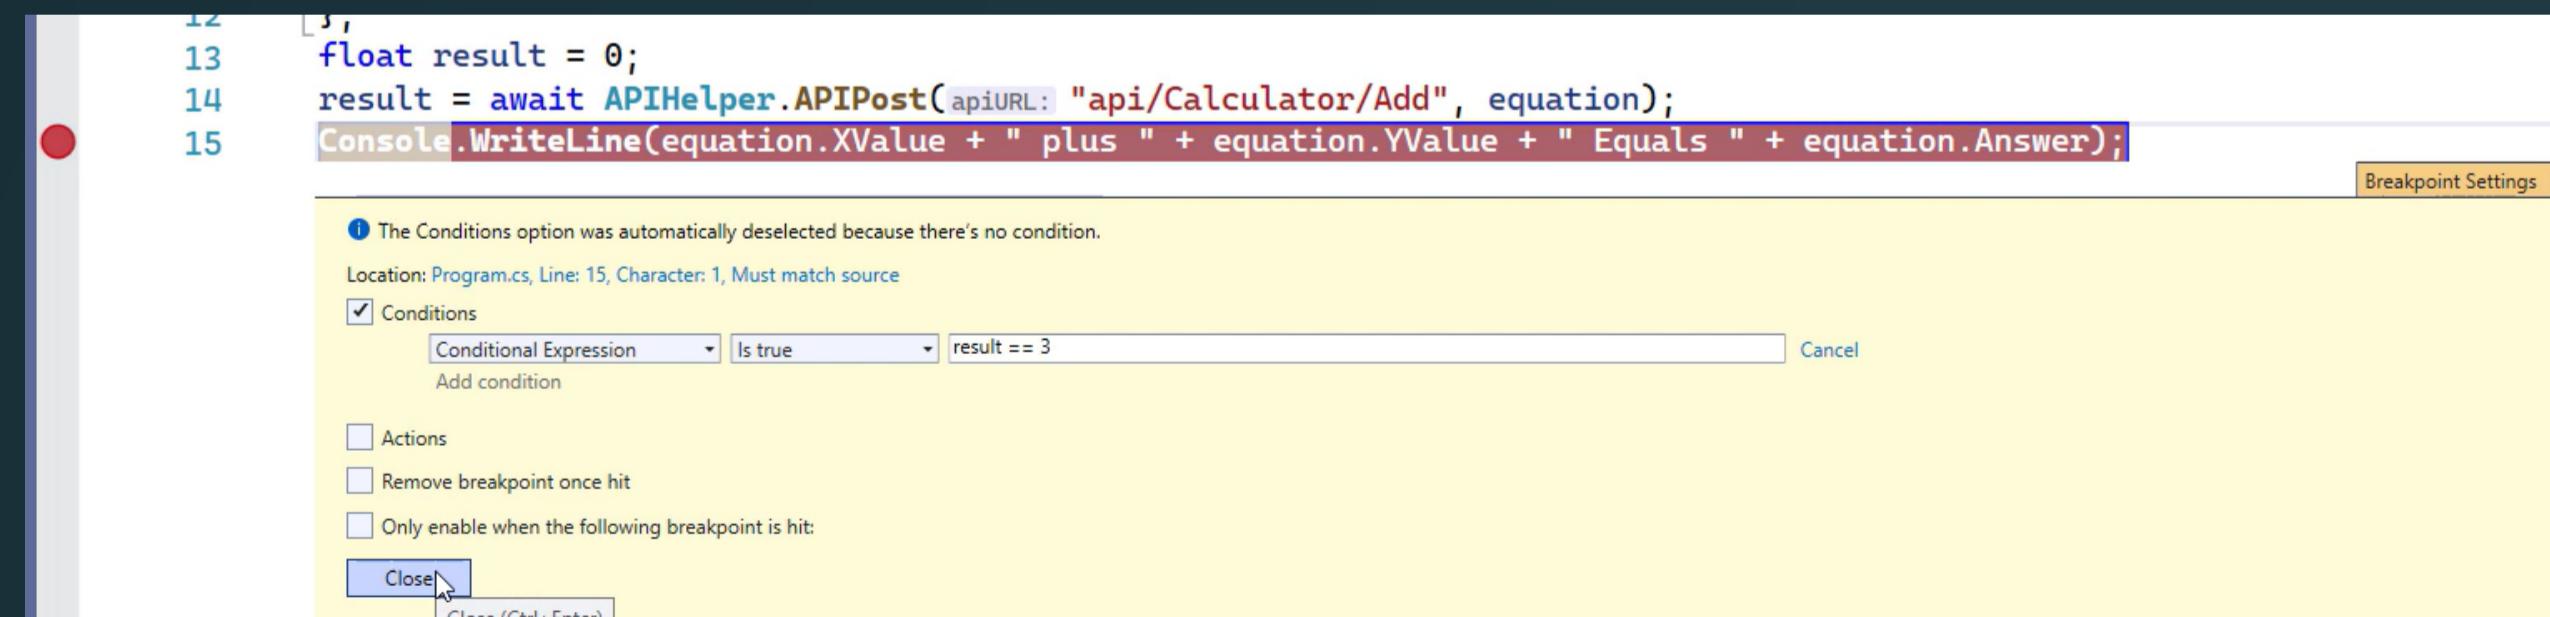

# Conditions

## Breakpoint Types:

- Standard Breakpoints: These are the regular breakpoints that pause the execution of the program when reached.
- Tracepoints: Tracepoints are special breakpoints that don't cause the program to pause but instead allow developers to log custom messages or perform specific actions when hit.
- Conditional Breakpoints: Conditional breakpoints are set with a condition, such as a specific variable value, and will only pause the execution if the condition is true.
- Hit Count Breakpoints: Hit count breakpoints pause the execution after a certain number of hits, useful for repetitive code or loops.

**Breakpoint Conditions:** Breakpoints can have conditions associated with them, allowing developers to specify when a breakpoint should be hit.

**Dependent Breakpoints:** Dependent breakpoints are breakpoints that are triggered only when a specific preceding breakpoint is hit.

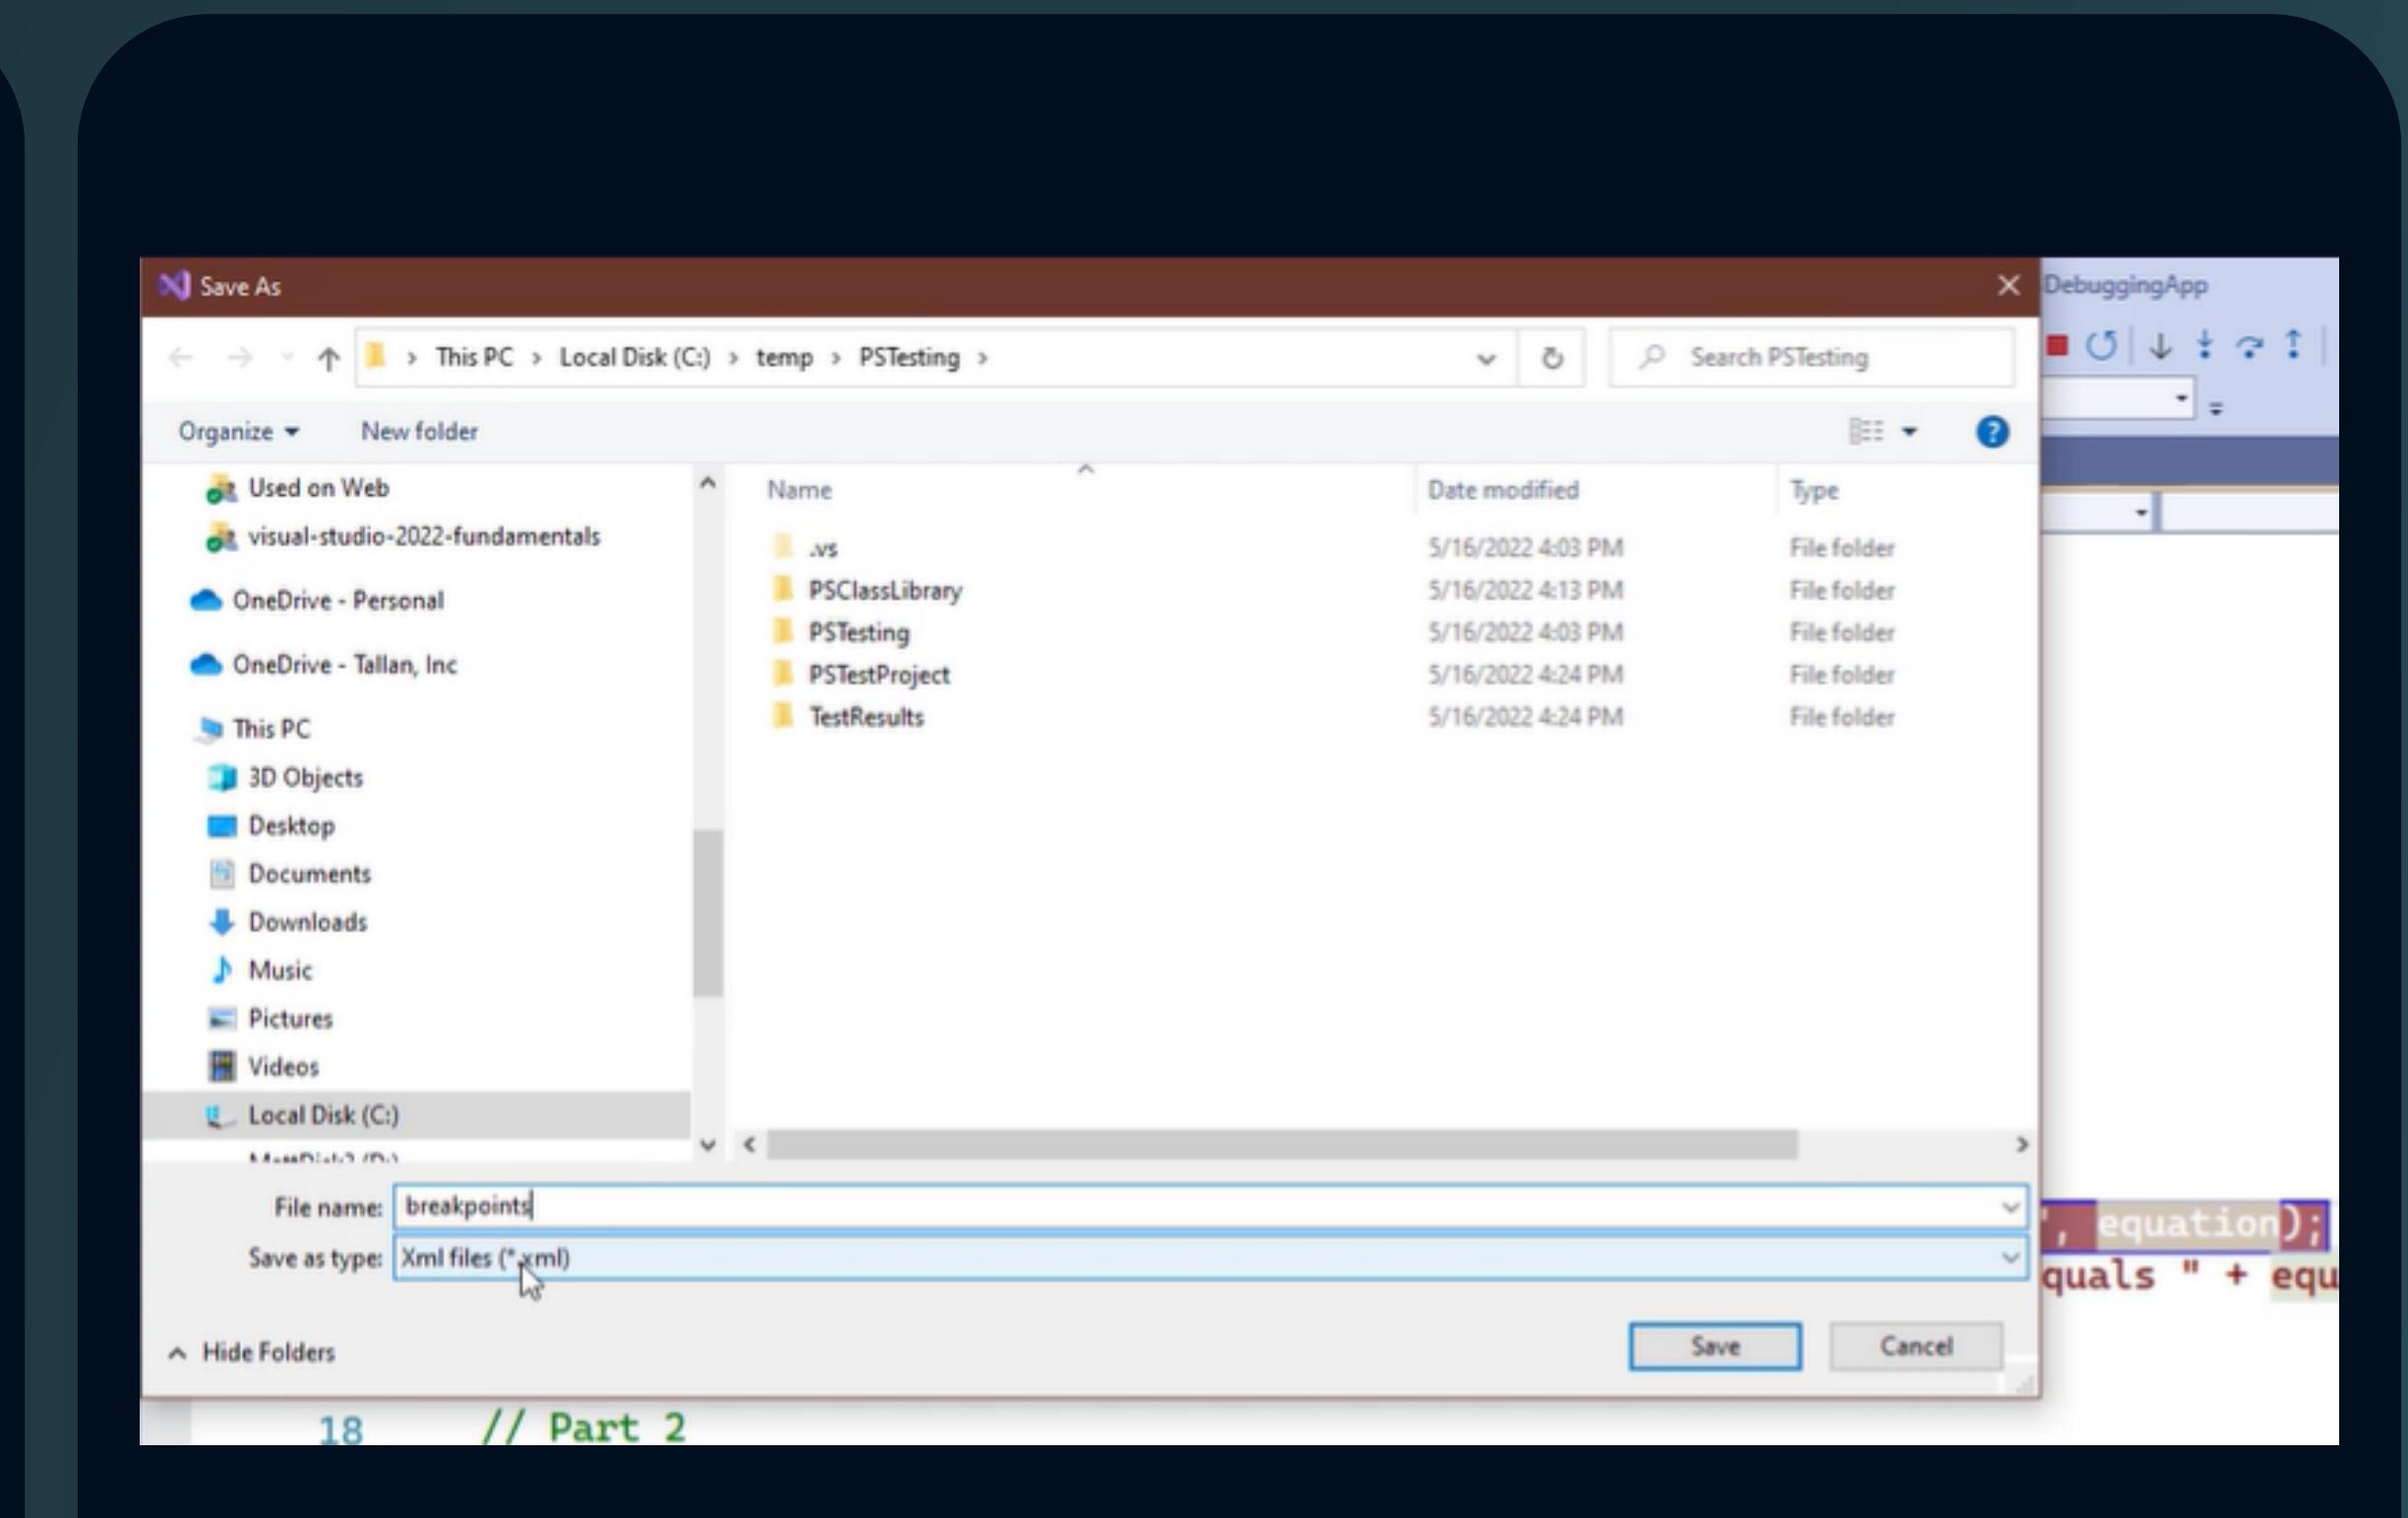

Using Condition to hit  
breakpoint

# Breakpoint View and Export

Breakpoint export is a feature in Visual Studio IDE that allows developers to export their configured breakpoints to share or reuse them across different development environments or with other team members.

The screenshot shows the Visual Studio IDE interface with several tabs open: Program.cs, APIHelper.cs, CalculatorController.cs, and Equation.cs. The code in Program.cs includes a breakpoint at line 15. The Breakpoints window is open, listing all configured breakpoints. One breakpoint for 'Program.cs, line 22 character 1' is selected and has its condition and hit count details visible. The status bar at the bottom indicates '150%' zoom.

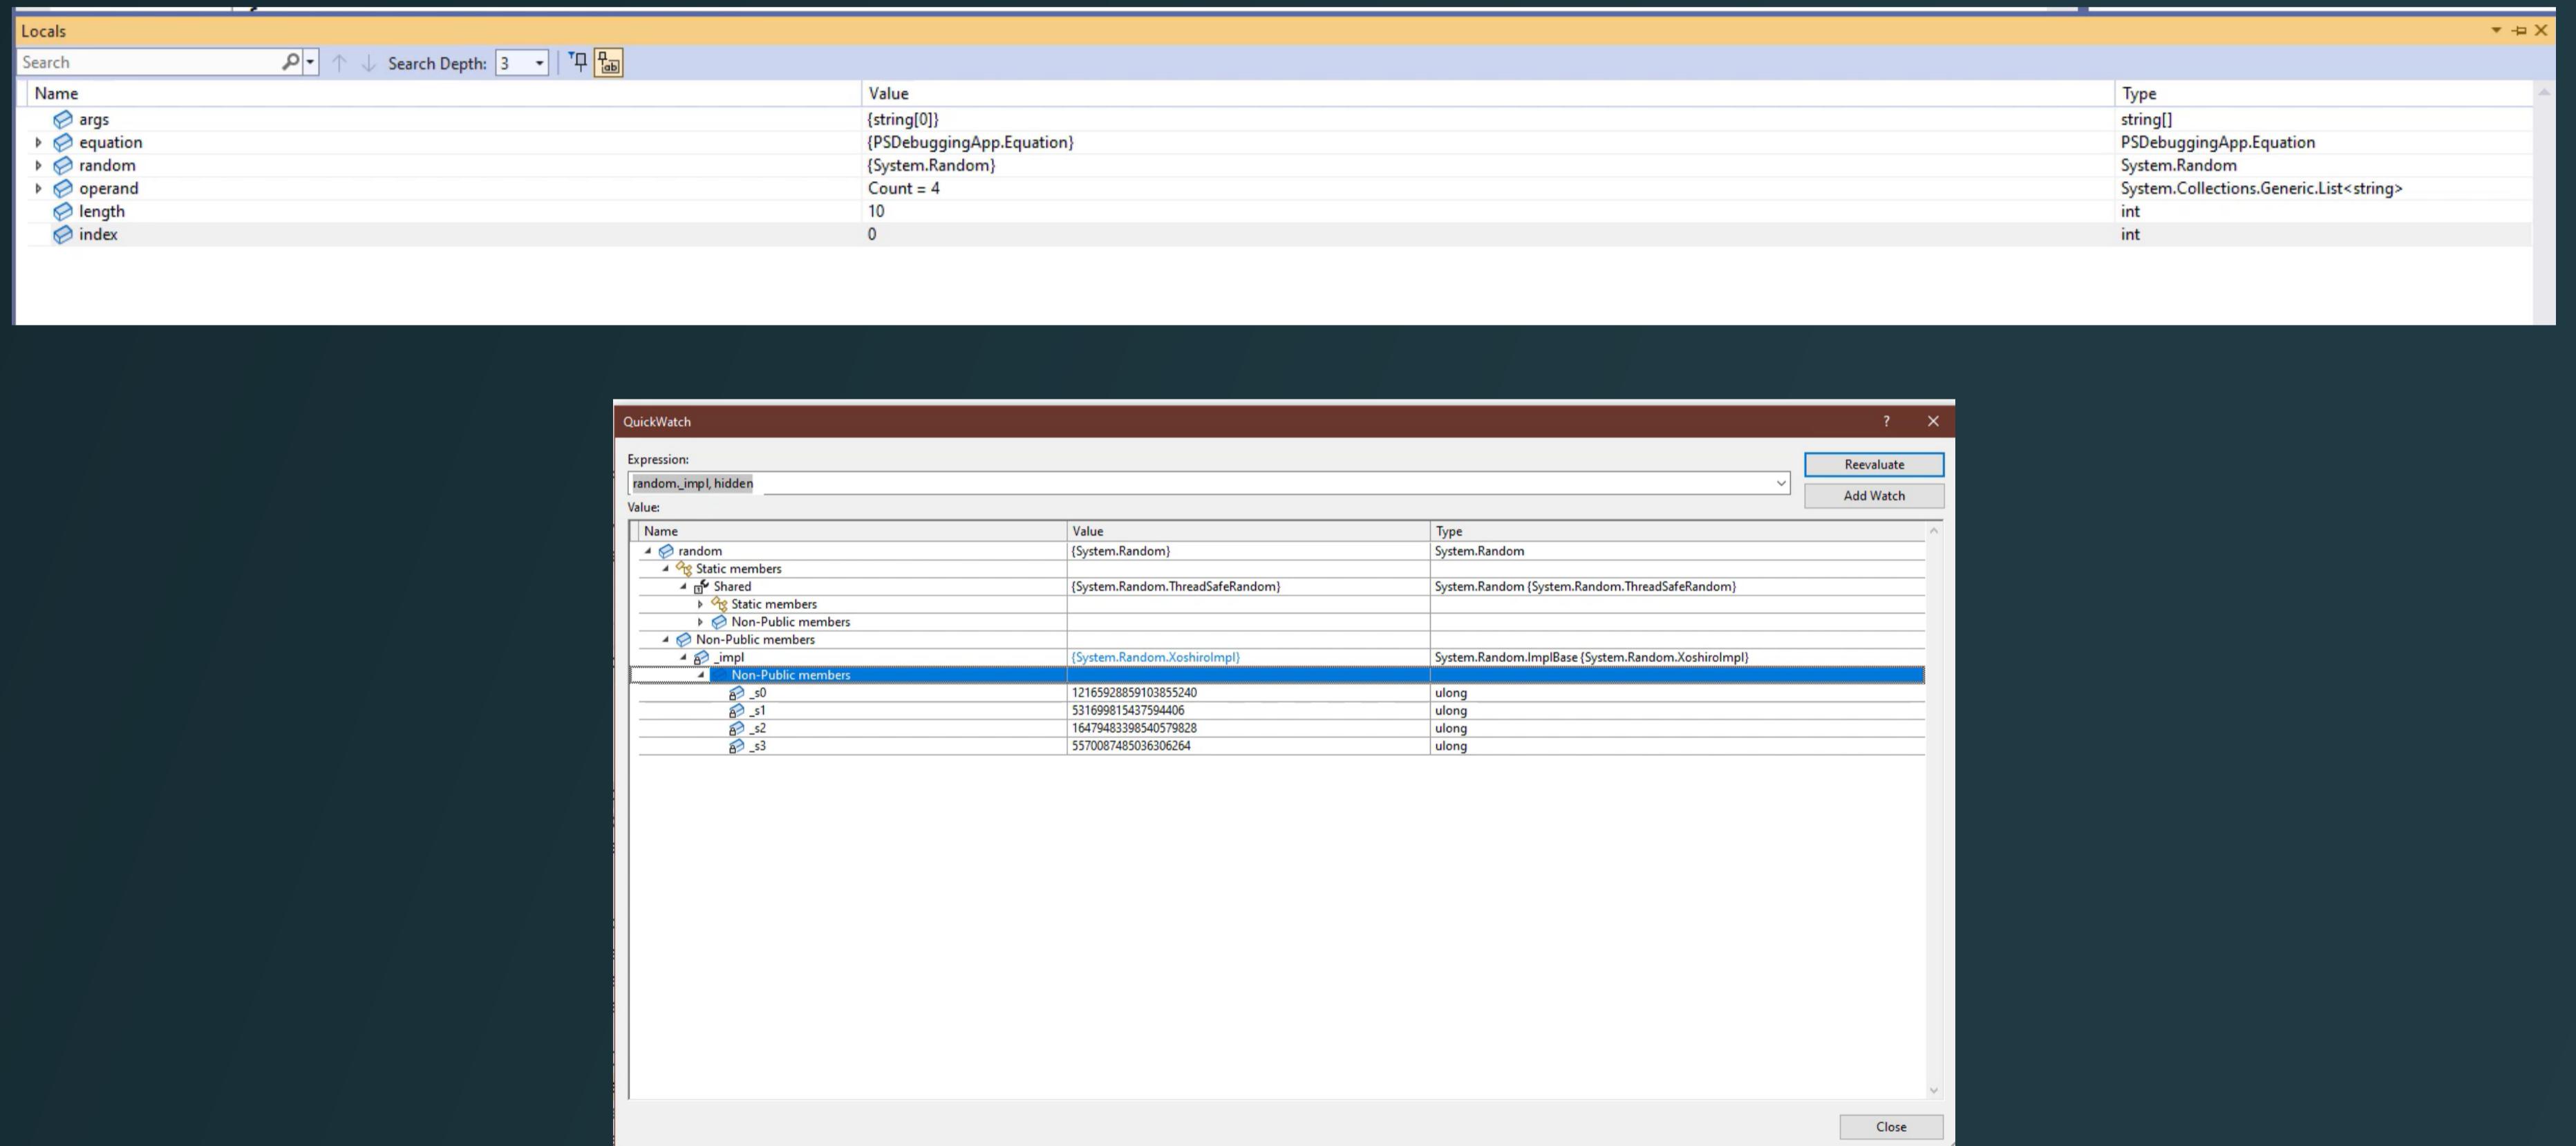

Break point view

Export break points

# Watch and quick watch

In Visual Studio IDE, the Watch and QuickWatch features are used during the debugging process to inspect and monitor the values of variables, expressions, and properties.

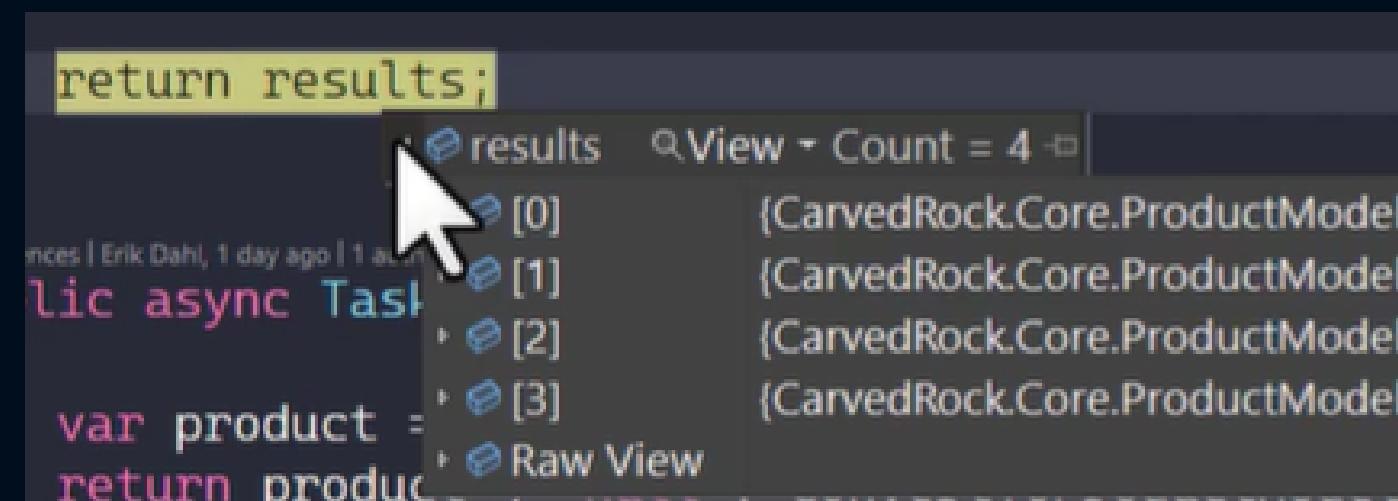

Watch - displays the current values of these items, these can be updated during debugging.

Quick watch - provides an on-the-spot evaluation of an expression or variable during debugging.

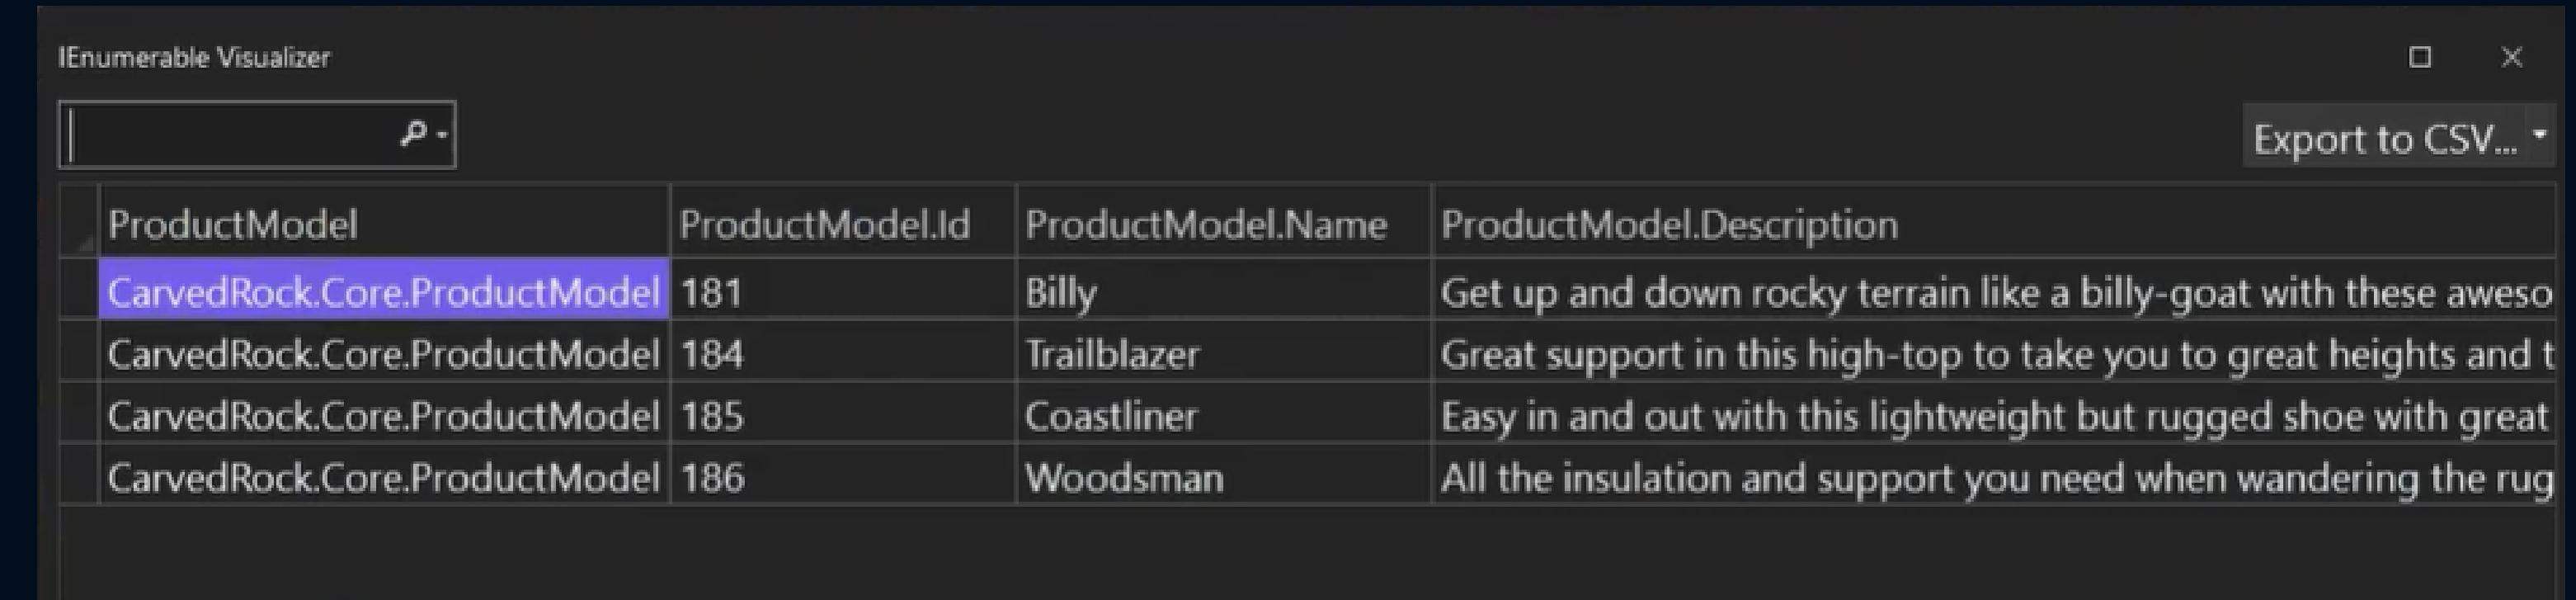

# Other debugger tools

The debugger can also display data inline, some of the information available is: scalar values, classes (uses default `ToString()`) , for collections you can use a visualizer and for strings visualizers are extended.

```
return results;
    ↴results View - Count = 4
      [0] (CarvedRock.Core.ProductModel)
      [1] (CarvedRock.Core.ProductModel)
      [2] (CarvedRock.Core.ProductModel)
      [3] (CarvedRock.Core.ProductModel)
var product =
return product
```

Debugger inline display

IEnumerable Visualizer			
P -			Export to CSV...
ProductModel	ProductModel.Id	ProductModel.Name	ProductModel.Description
CarvedRock.Core.ProductModel	181	Billy	Get up and down rocky terrain like a billy-goat with these aweso
CarvedRock.Core.ProductModel	184	Trailblazer	Great support in this high-top to take you to great heights and t
CarvedRock.Core.ProductModel	185	Coastliner	Easy in and out with this lightweight but rugged shoe with great
CarvedRock.Core.ProductModel	186	Woodsman	All the insulation and support you need when wandering the rug

Debugger Visualizer

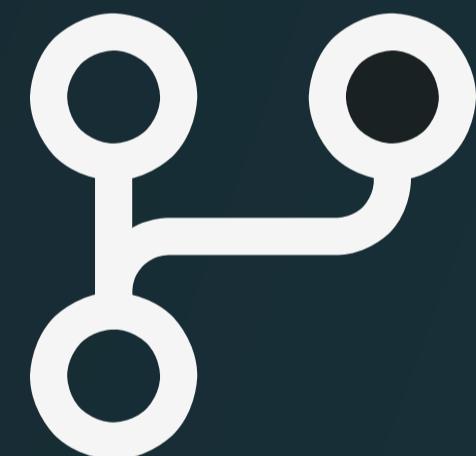

# Demo

[C# fundamentals](#)

# Tasks

## Quick Exercises

Create a Console application that gives the user 2 options:

1. Input Commands
2. Show categories
3. Exit

When selecting 1 the user can input anything, this information should be categorized between text and numbers, and separated in different collections.

When selecting 2 the user should see a List of Text commands and a List of Numeric commands.

When selecting 3 the application should terminate its execution
